
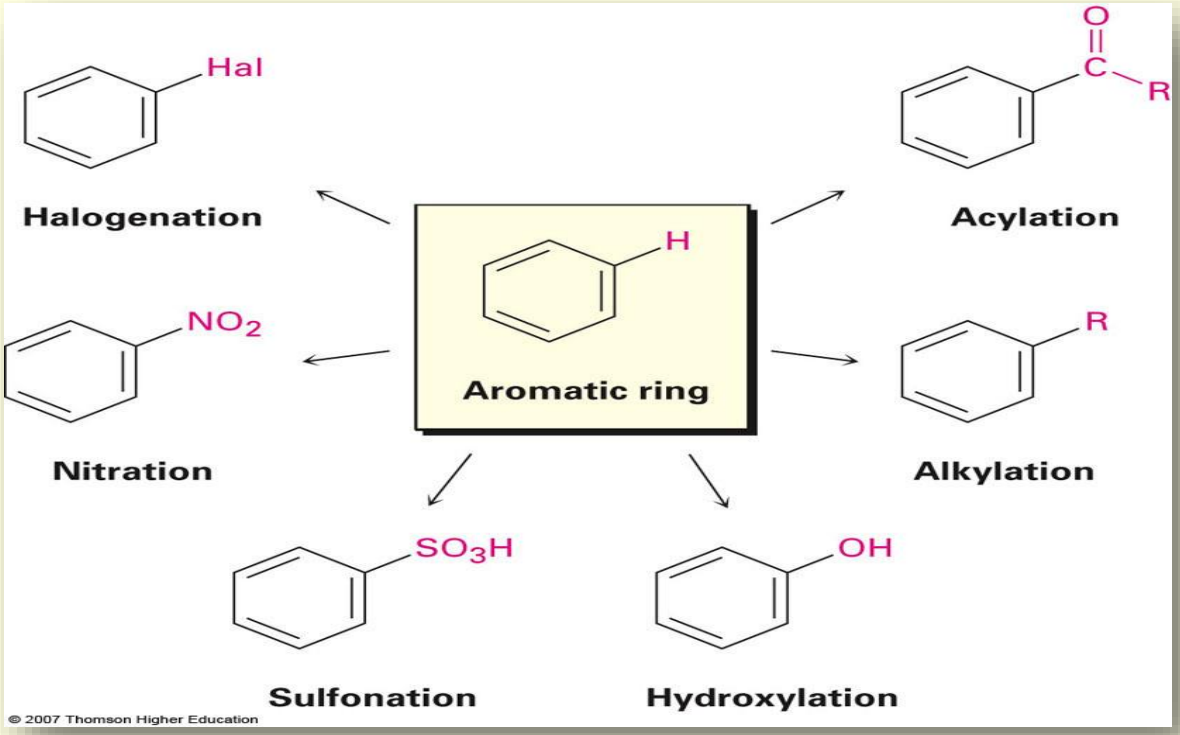
Chemistry of Benzene Electrophilic Aromatic Substitution

Based on McMurry's *Organic Chemistry*, 7th edition

Assistant Lecturer. Jalal Hasan Mohammed

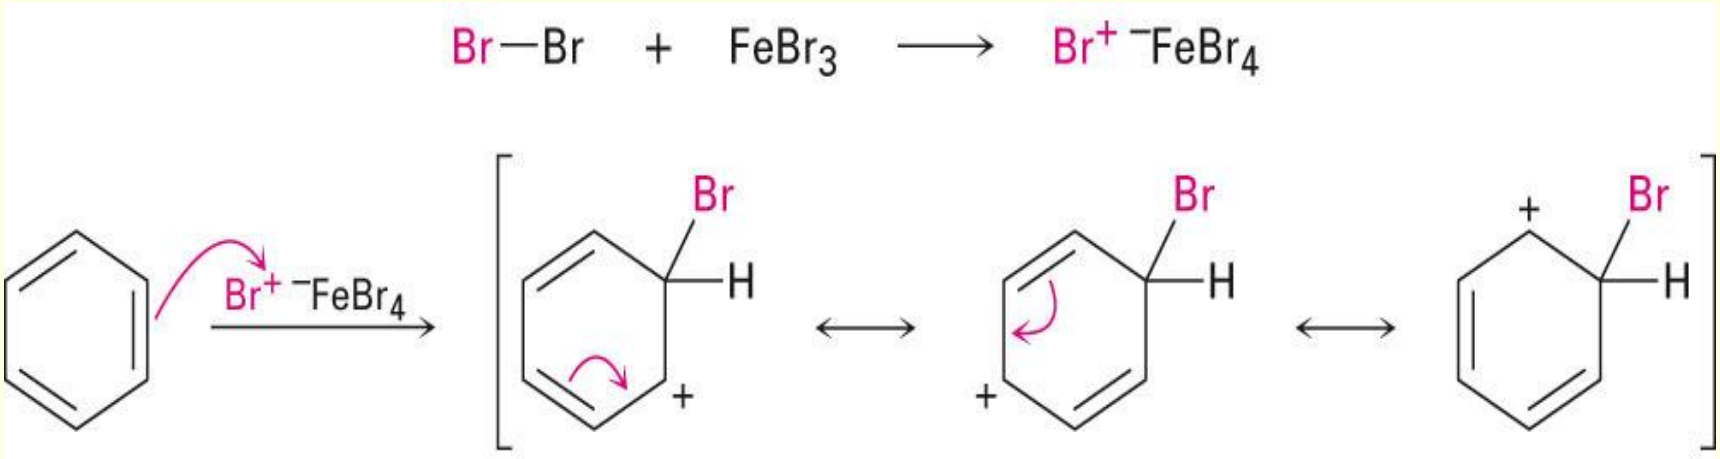
Substitution Reactions of Benzene and Its Derivatives

- Benzene is aromatic: a cyclic conjugated compound with 6 π electrons
- Reactions of benzene lead to the retention of the aromatic core.



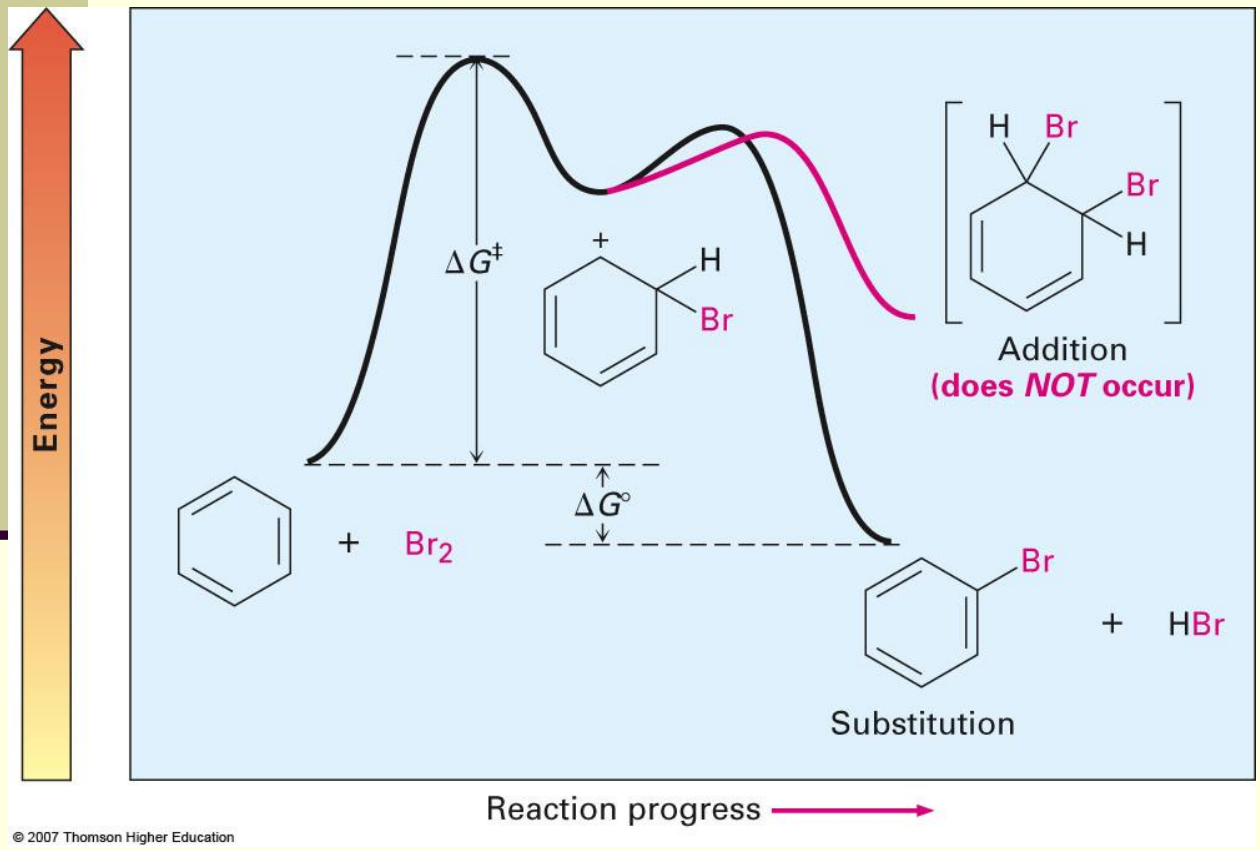
Electrophilic Aromatic Bromination

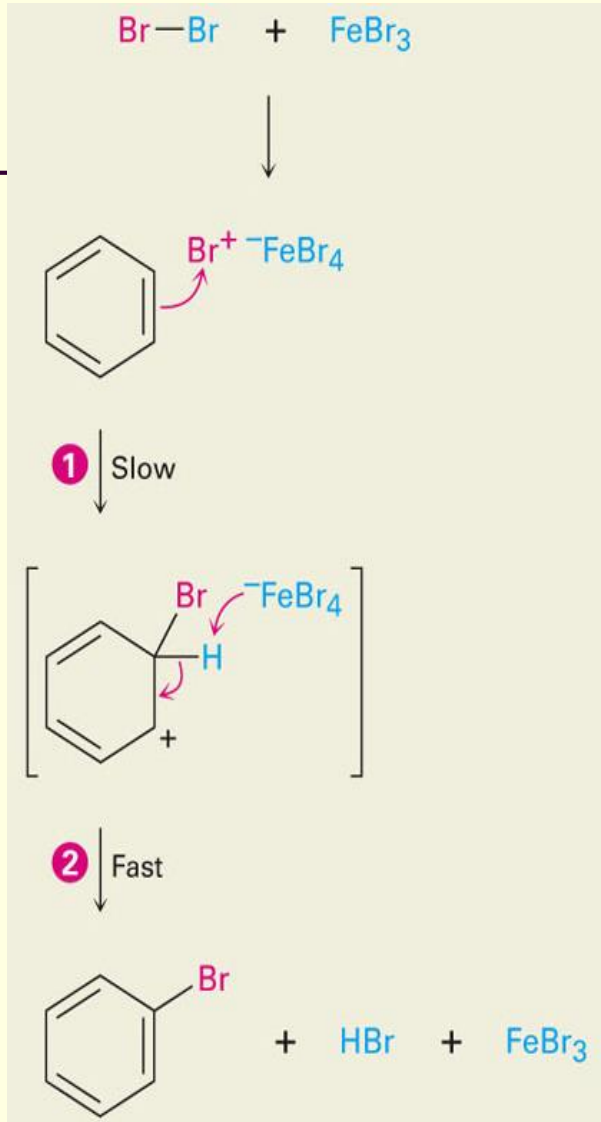
- Benzene's π electrons participate as a Lewis base in reactions with Lewis acids
- The product is formed by loss of a proton, which is replaced by bromine
- $FeBr_3$ is added as a catalyst to polarize the bromine reagent
- In the first step the π electrons act as a nucleophile toward Br_2 (in a complex with $FeBr_3$)
- This forms a cationic addition intermediate from benzene and a bromine cation
- The intermediate is not aromatic and therefore high in energy



Formation of Product from Intermediate

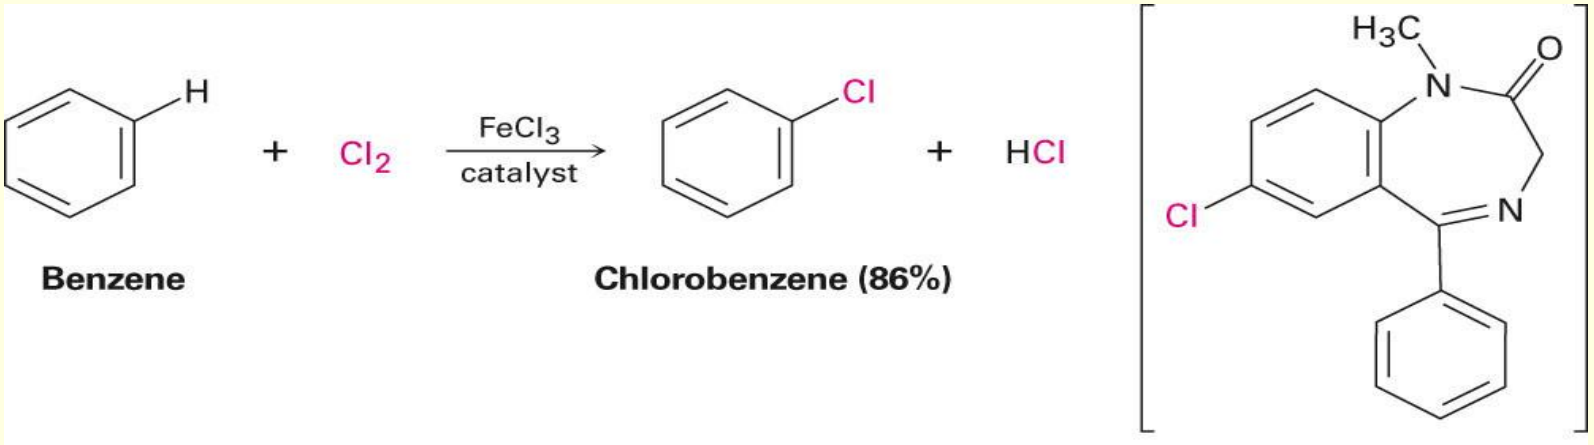
- The cationic addition intermediate transfers a proton to $FeBr_4^-$ (from Br^- and $FeBr_3$)
- This restores aromaticity (in contrast with addition in alkenes)



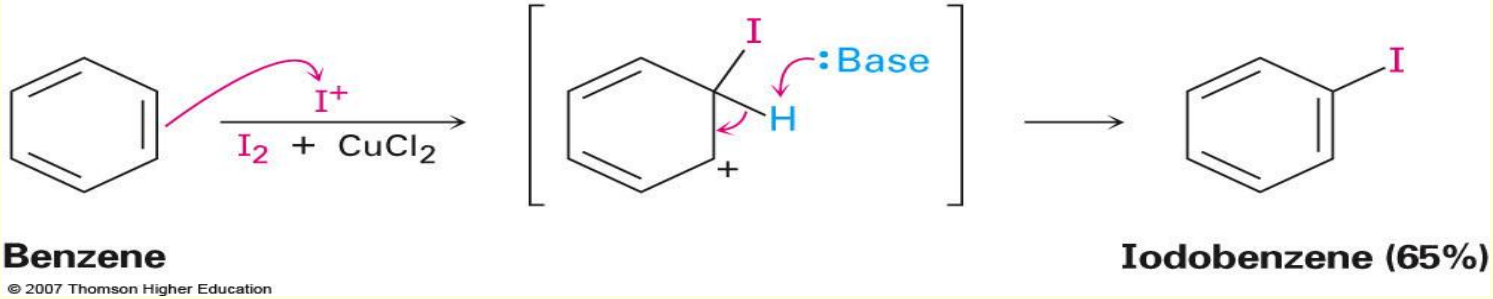


Other Aromatic Halogenations

- Chlorine and iodine (but not fluorine, which is too reactive) can produce aromatic substitution with the addition of other reagents to promote the reaction
- Chlorination requires $FeCl_3$
- Iodine must be oxidized to form a more powerful I^+ species (with Cu^{2+} from $CuCl_2$)

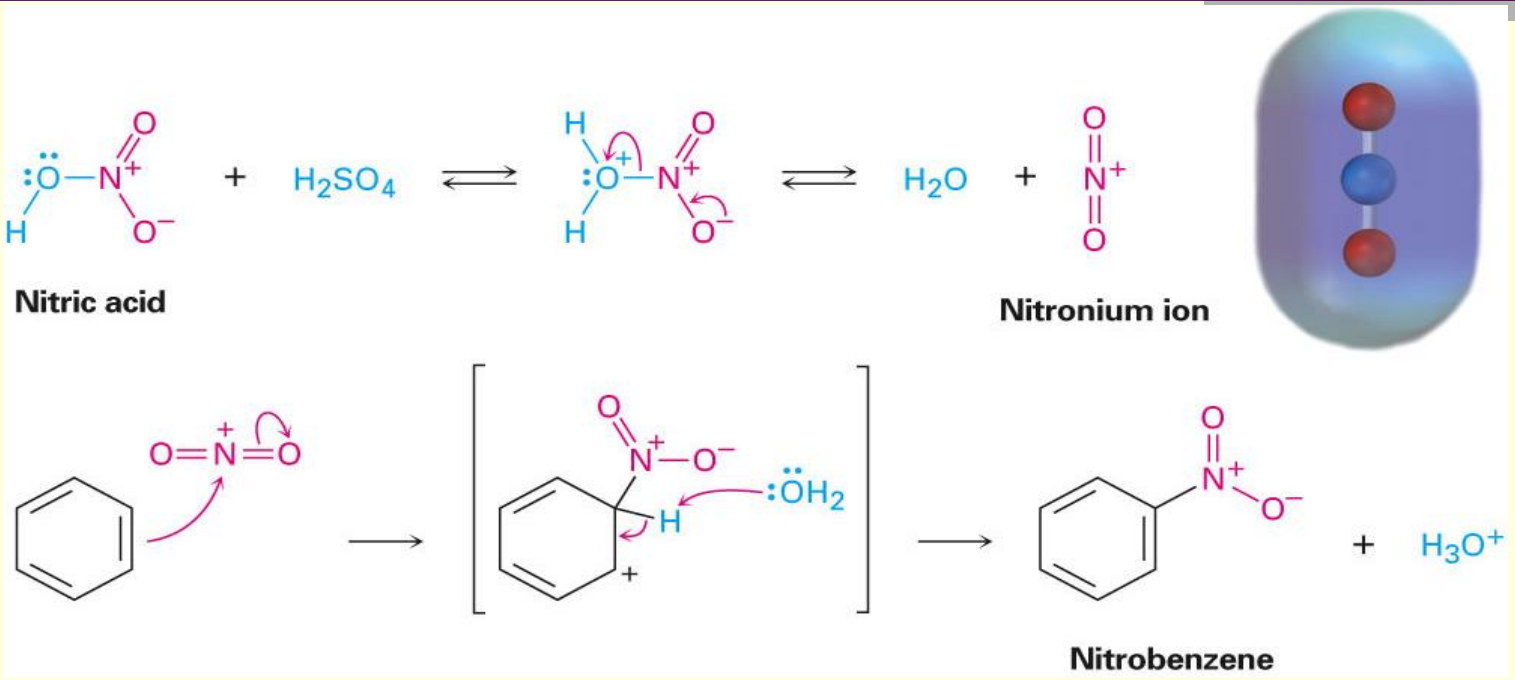


$$I_2 + 2\,Cu^{2+} \longrightarrow 2\,I^+ + 2\,Cu^+$$

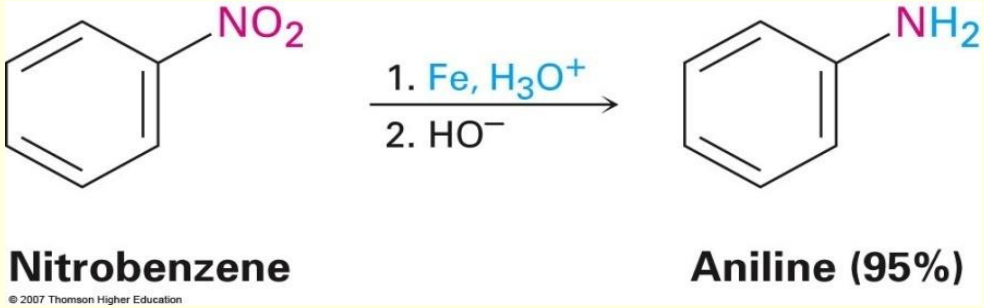


Aromatic Nitration

- The combination of nitric acid and sulfuric acid produces NO_2^+ (nitronium ion)
- The reaction with benzene produces nitrobenzene

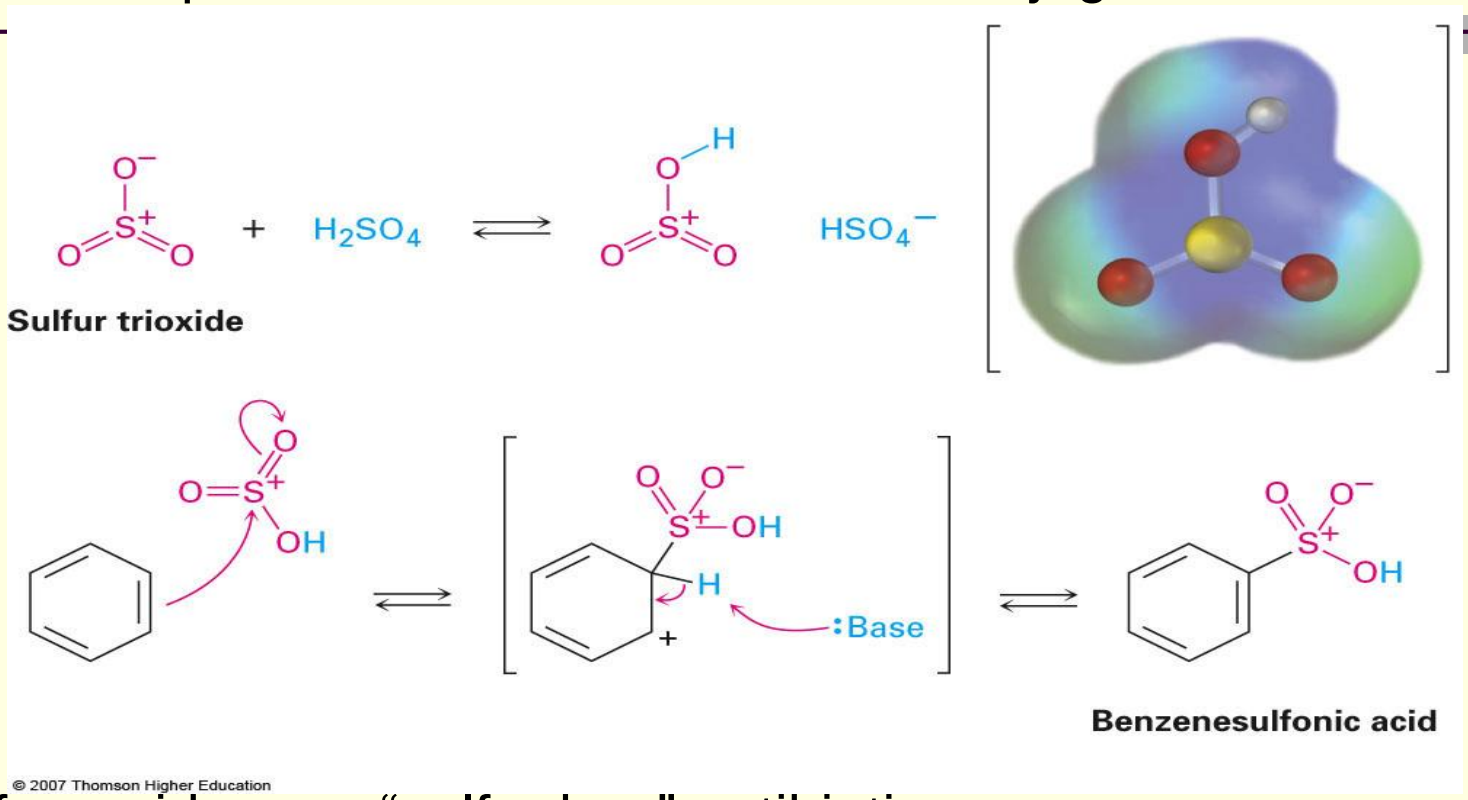


- The Nitro group can be reduced to an Amino group if needed

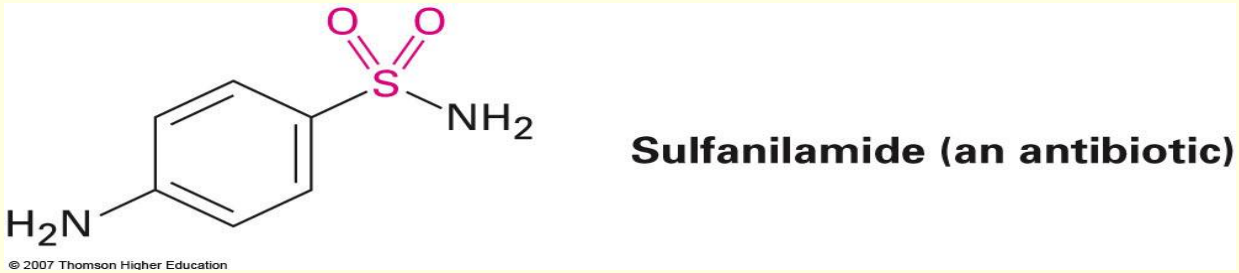


Aromatic Sulfonation

- Substitution of H by SO_3 (sulfonation)
- Reaction with a mixture of sulfuric acid and SO_3 ("Fuming H_2SO_4)
- Reactive species is sulfur trioxide or its conjugate acid

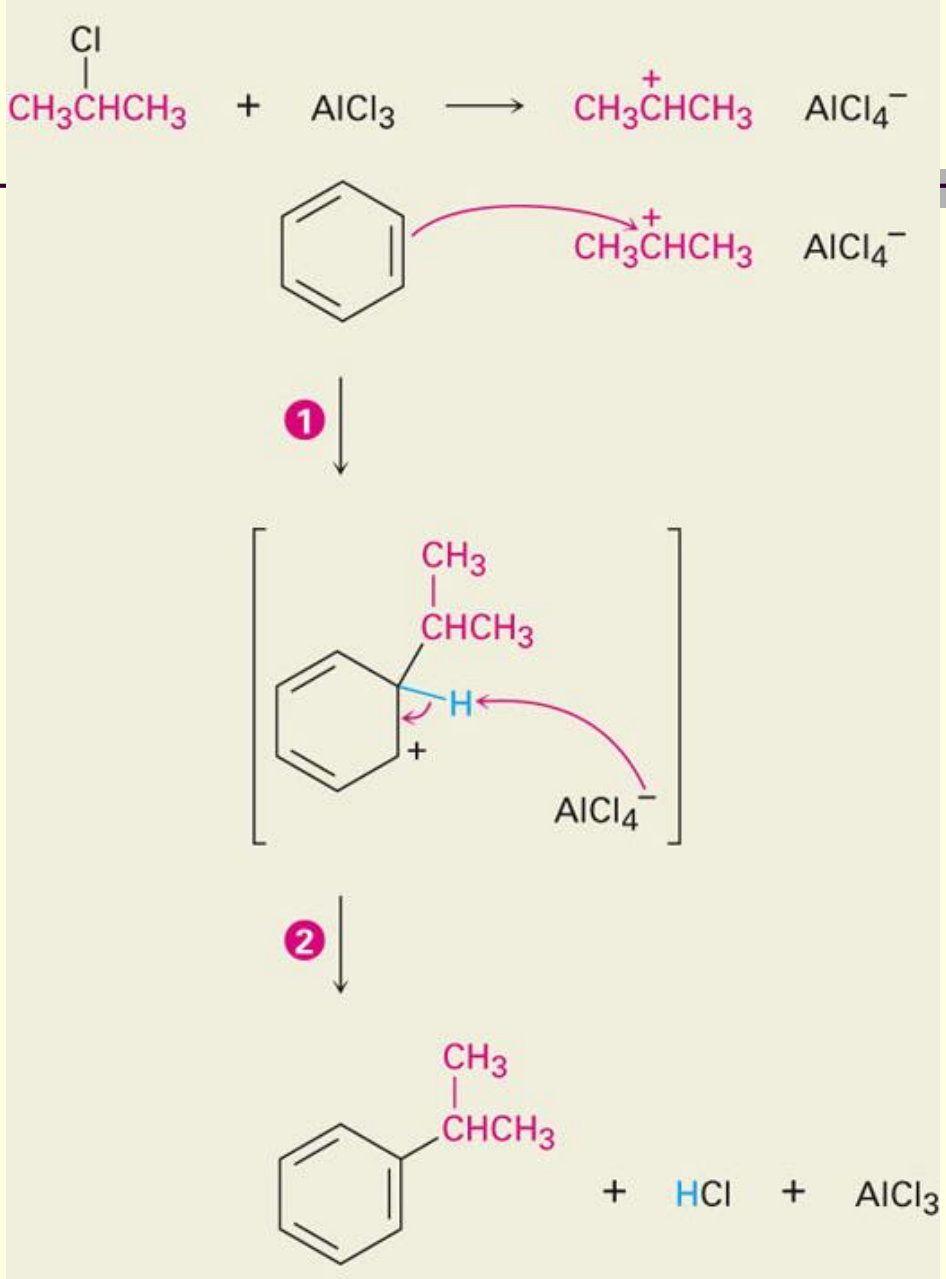


- Sulfonamides are "sulfa drug" antibiotics



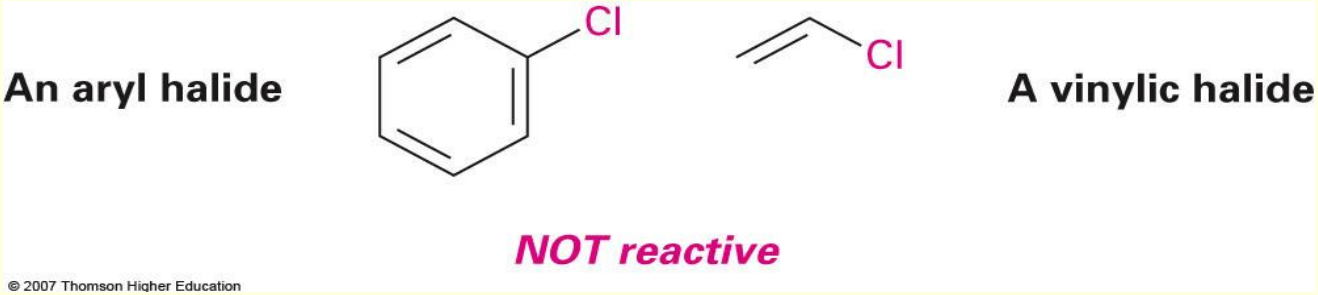
Alkylation of Aromatic Rings: The Friedel–Crafts Reaction

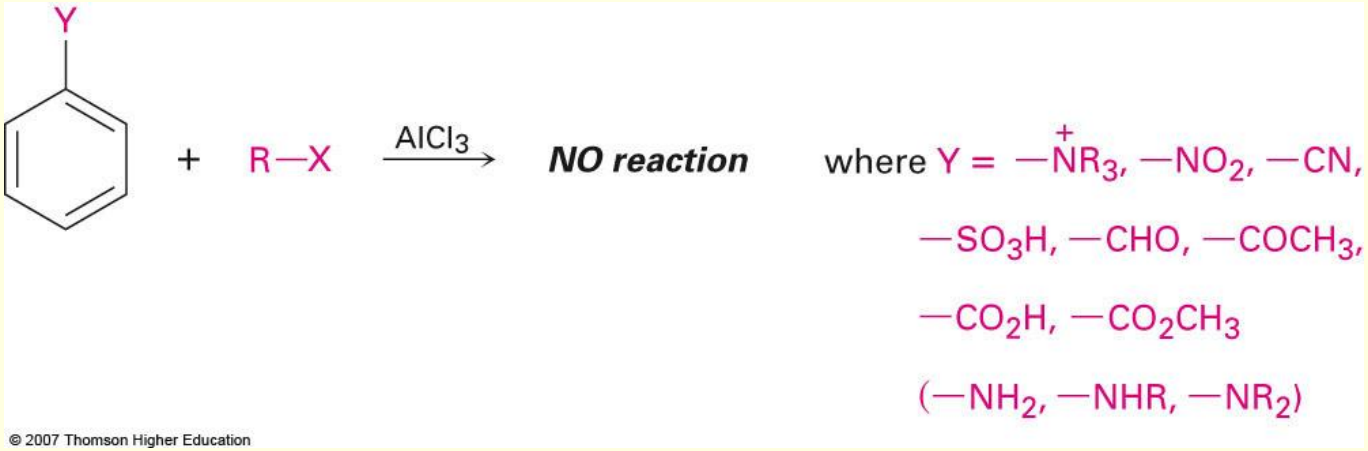
- Alkylation among most useful electrophilic aromatic substitution reactions
- Aromatic substitution of R^+ for H^+
- Aluminum chloride promotes the formation of the carbocation



Limitations of the Friedel-Crafts Alkylation

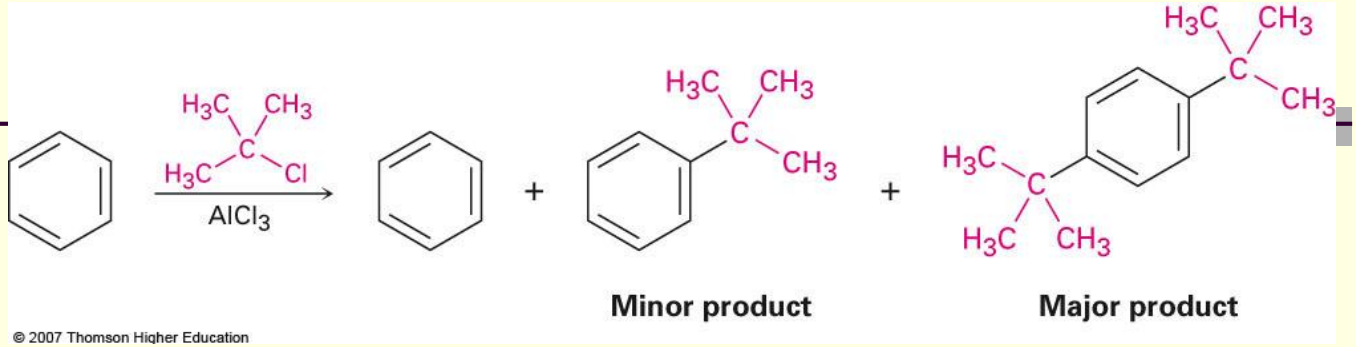
- Only *alkyl* halides can be used (F, Cl, I, Br)
- *Aryl* halides and *vinylic* halides do not react (their carbocations are too hard to form)
- Will not work with rings containing an amino group substituent or a strongly electron-withdrawing group



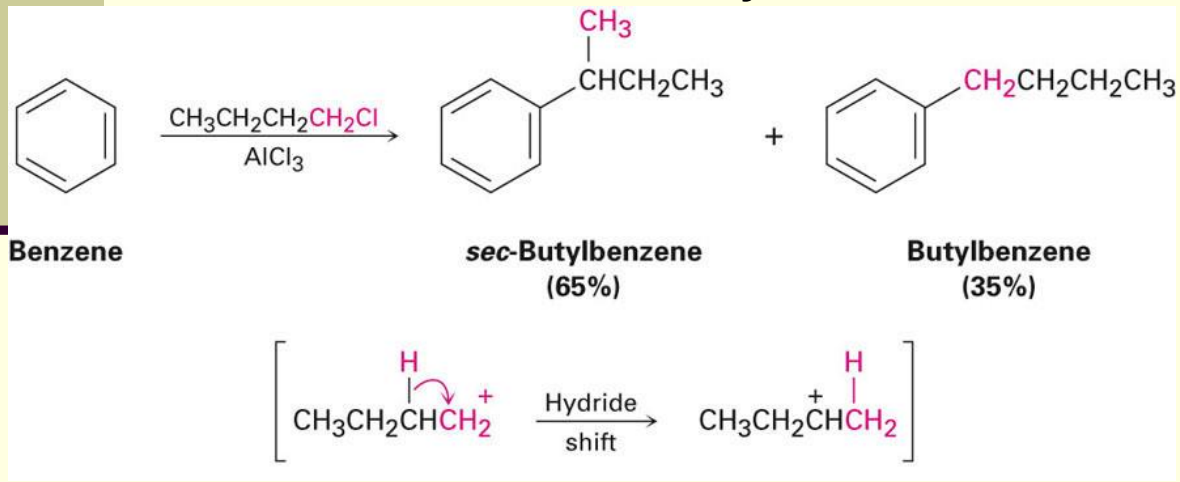


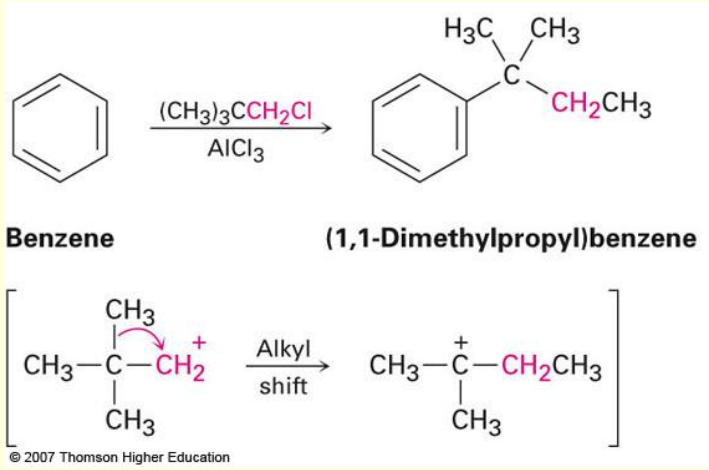
Other Problems with Alkylation

- Multiple alkylations can occur because the first alkylation is activating



- Carbocation Rearrangements Occur During Alkylation
  - Similar to those occuring during electrophilic additions to alkene
  - Can involve H or alkyl shifts



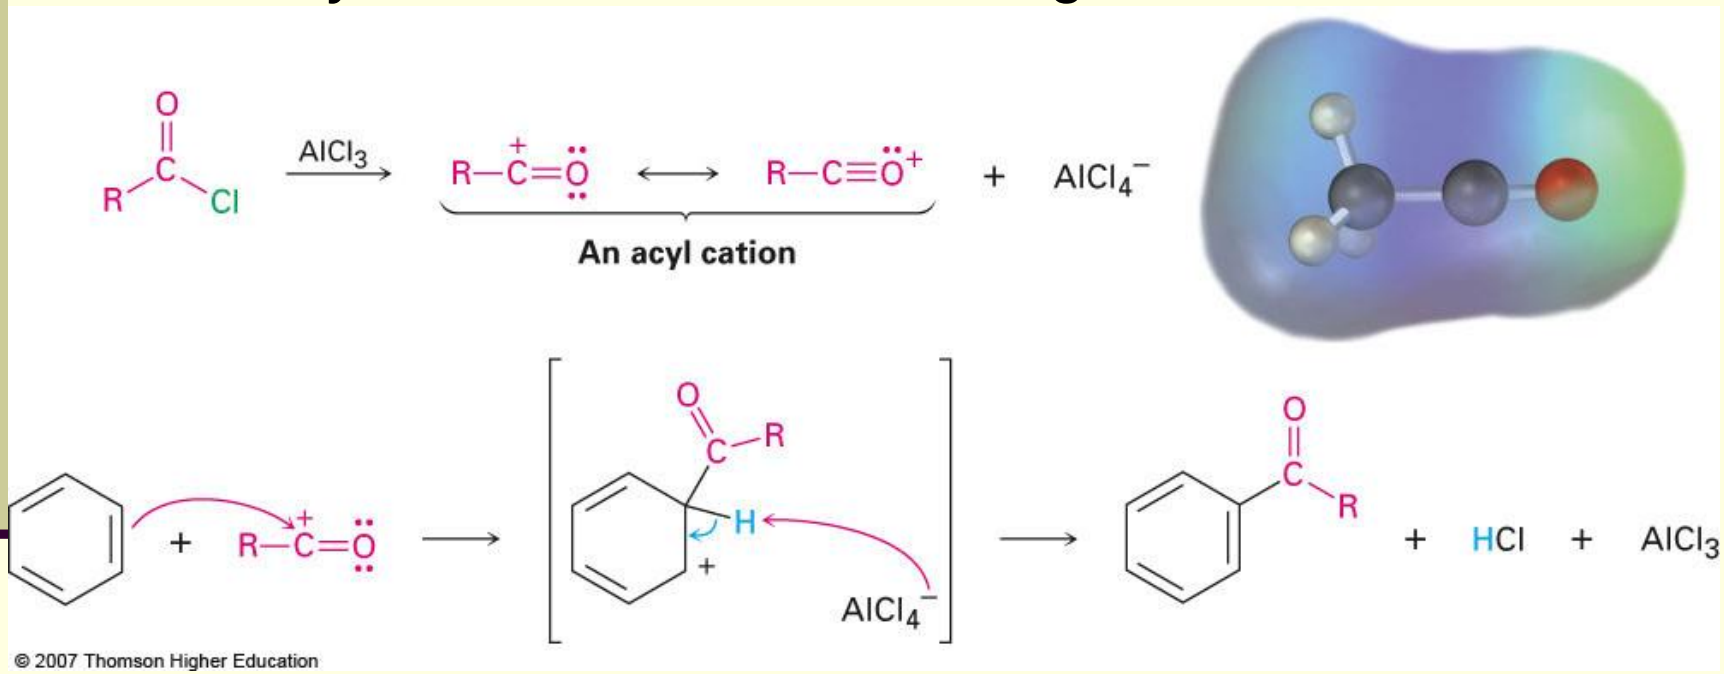


Acylation of Aromatic Rings

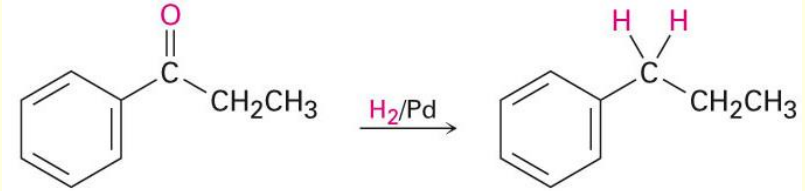
- Reaction of an acid chloride (RCOCl) and an aromatic ring in the presence of $AlCl_3$ introduces **acyl group**, —COR
  - Benzene with acetyl chloride yields acetophenone
  - 
- Avoids many of the problems of alkylation
  - Only substitutes once, because acyl group is deactivating
  - No rearrangement because of resonance stabilized cation

Mechanism of Friedel-Crafts Acylation

- Similar to alkylation
- Reactive electrophile: resonance-stabilized acyl cation
- An acyl cation does not rearrange

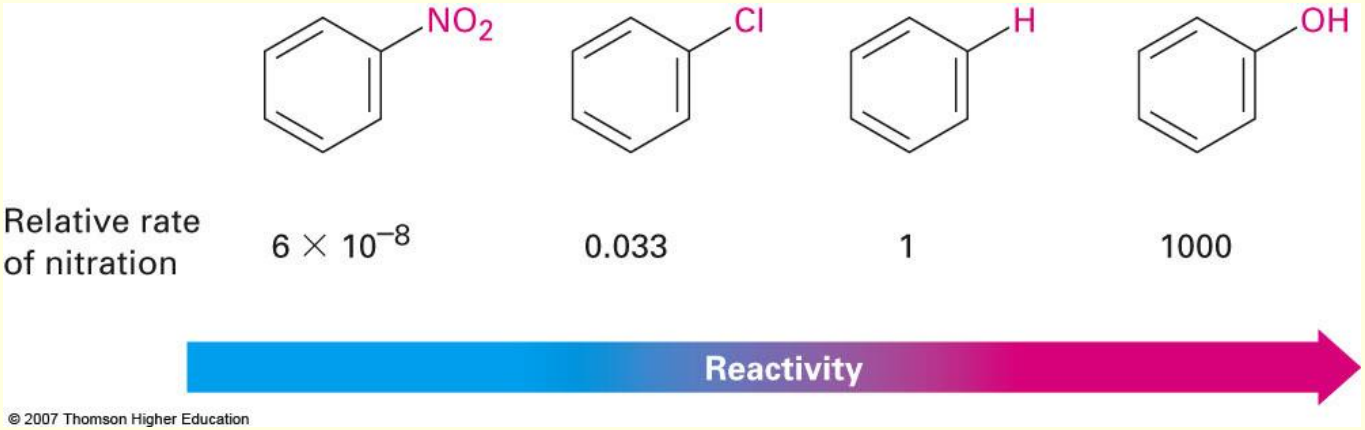


- Can reduce carbonyl to get alkyl product



Substituent Effects in Aromatic Rings

- Substituents can cause a compound to be (much) more or (much) less reactive than benzene



- Substituents affect the orientation of the reaction – the positional relationship is controlled

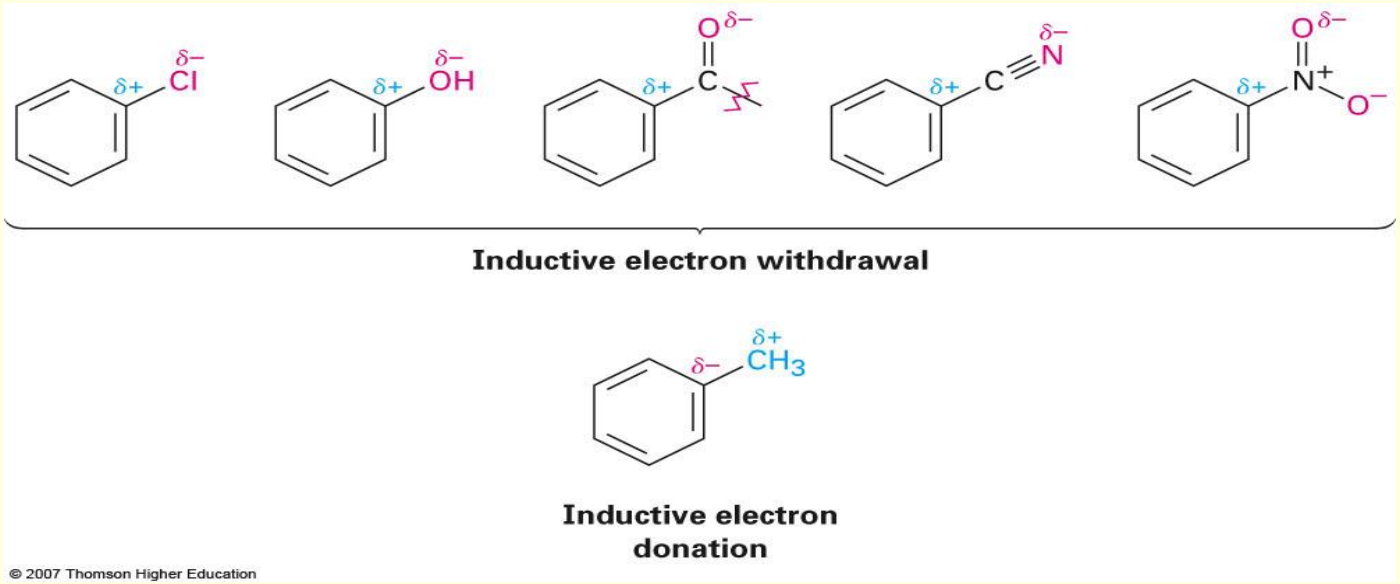
- ortho- and para-directing activators, ortho- and para-directing deactivators, and meta-directing deactivators.

Origins of Substituent Effects

- An interplay of *inductive effects* and *resonance effects*
- Inductive effect - withdrawal or donation of electrons ***through a σ bond*** = Polar Covalent Bonds
- Resonance effect - withdrawal or donation of electrons ***through a π bond*** due to the overlap of a *p* orbital on the substituent with a *p* orbital on the aromatic ring

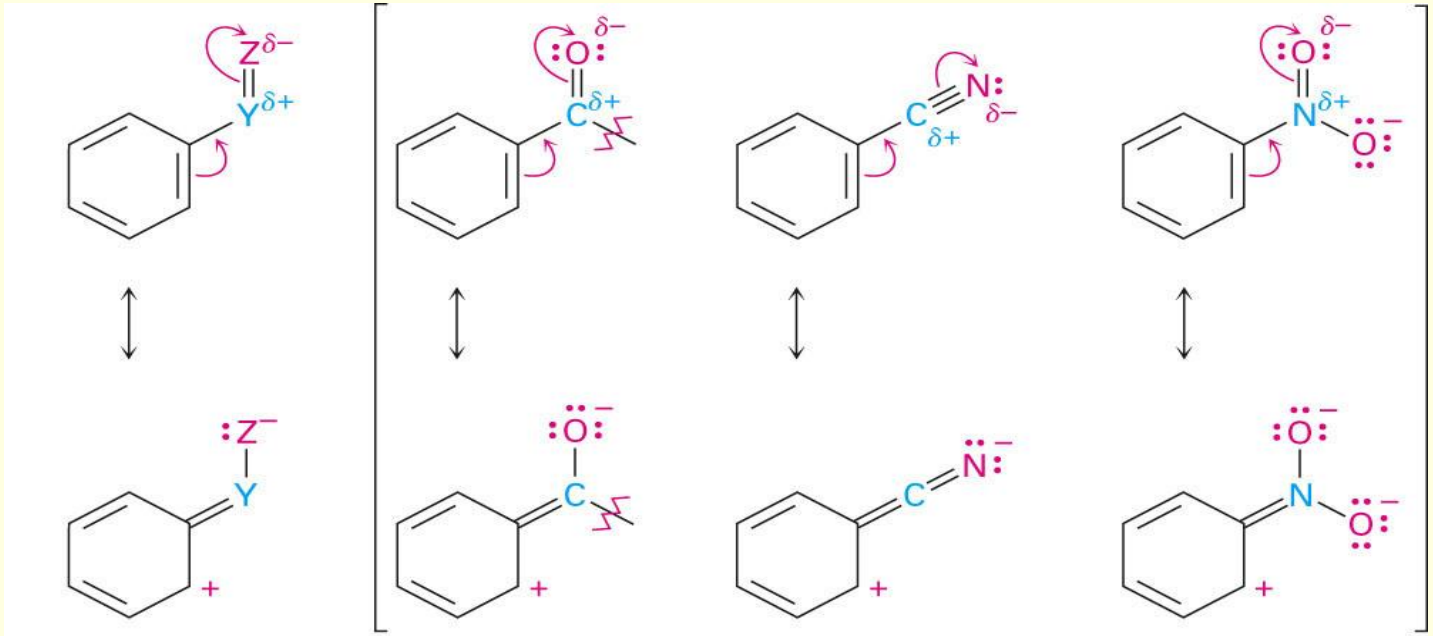
Inductive Effects

- Controlled by electronegativity and the polarity of bonds in functional groups
- Halogens, C=O, CN, and NO_2 *withdraw* electrons through σ bond connected to ring
- Alkyl groups *donate* electrons



Resonance Effects – Electron Withdrawal

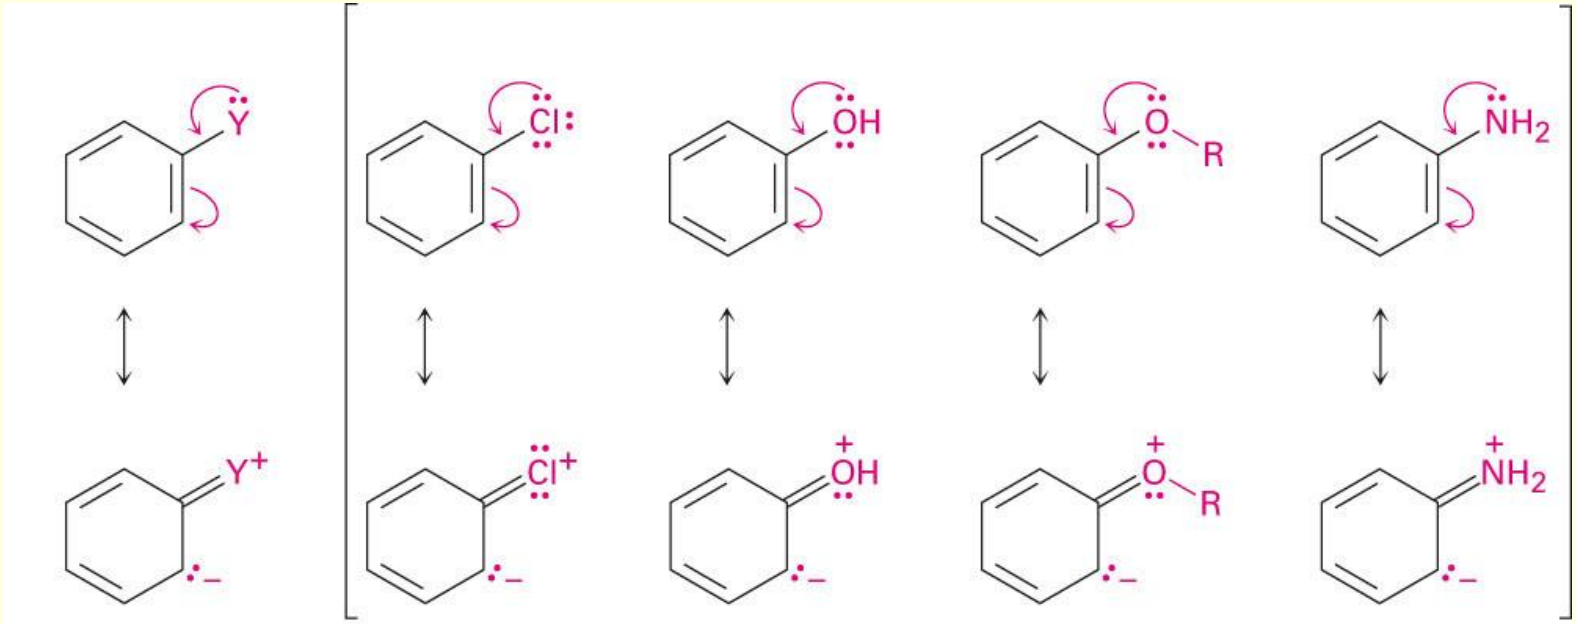
- C=O, CN, NO_2 substituents *withdraw* electrons from the aromatic ring by resonance
- π electrons flow from the rings to the substituents
- ***Look for a double (or triple) bond connected to the ring by a single bond***



Resonance electron-withdrawing group

Resonance Effects – Electron Donation

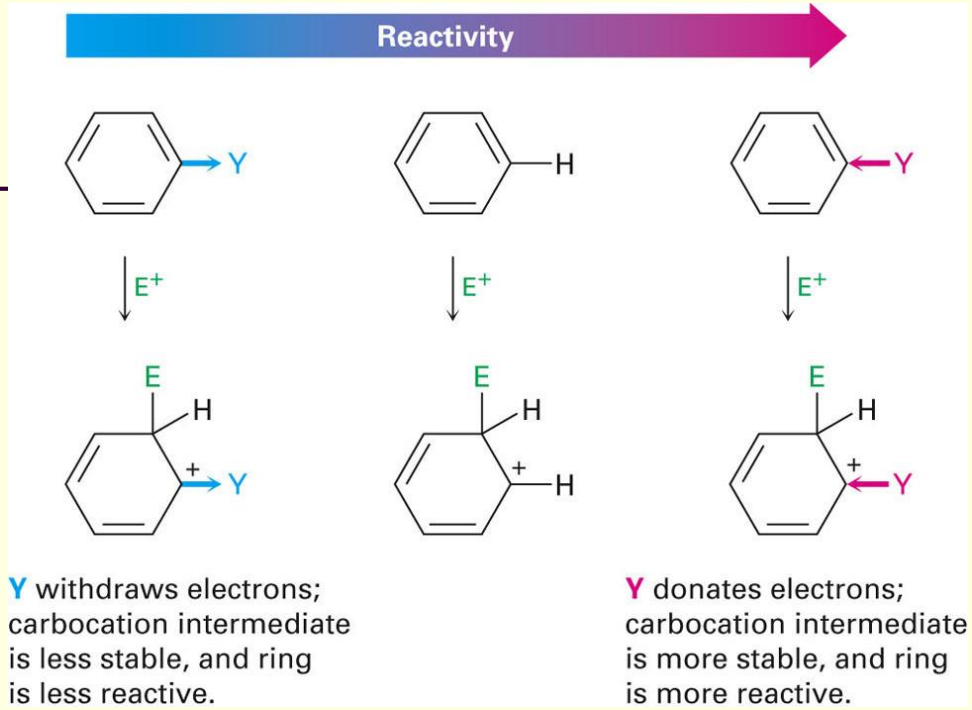
- Halogen, OH, alkoxyl (OR), and amino substituents *donate* electrons
- π electrons flow from the substituents to the ring
- Effect is greatest at ortho and para positions
- ***Look for a lone pair on an atom attached to the ring***

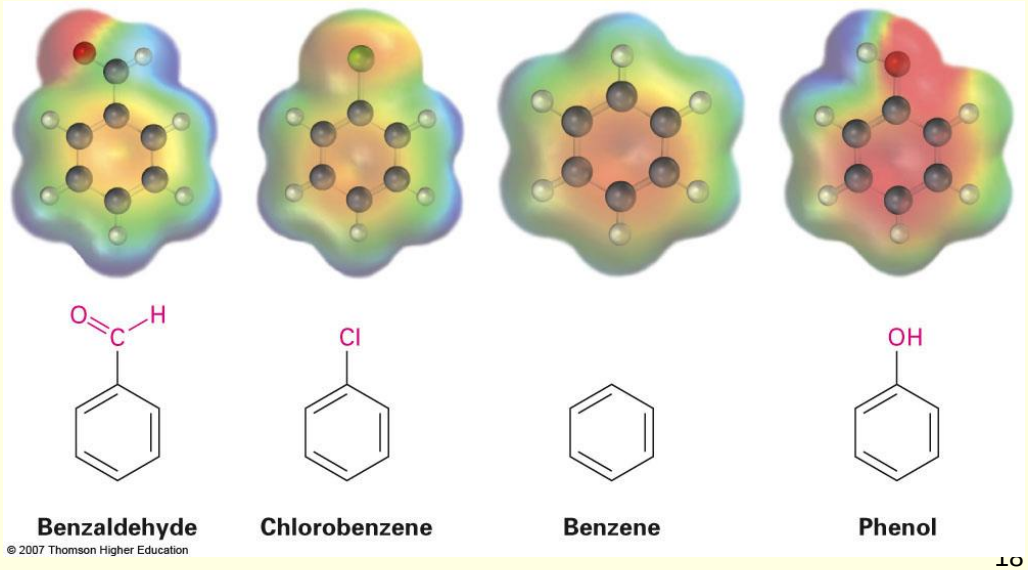


Resonance electron-donating group

An Explanation of Substituent Effects

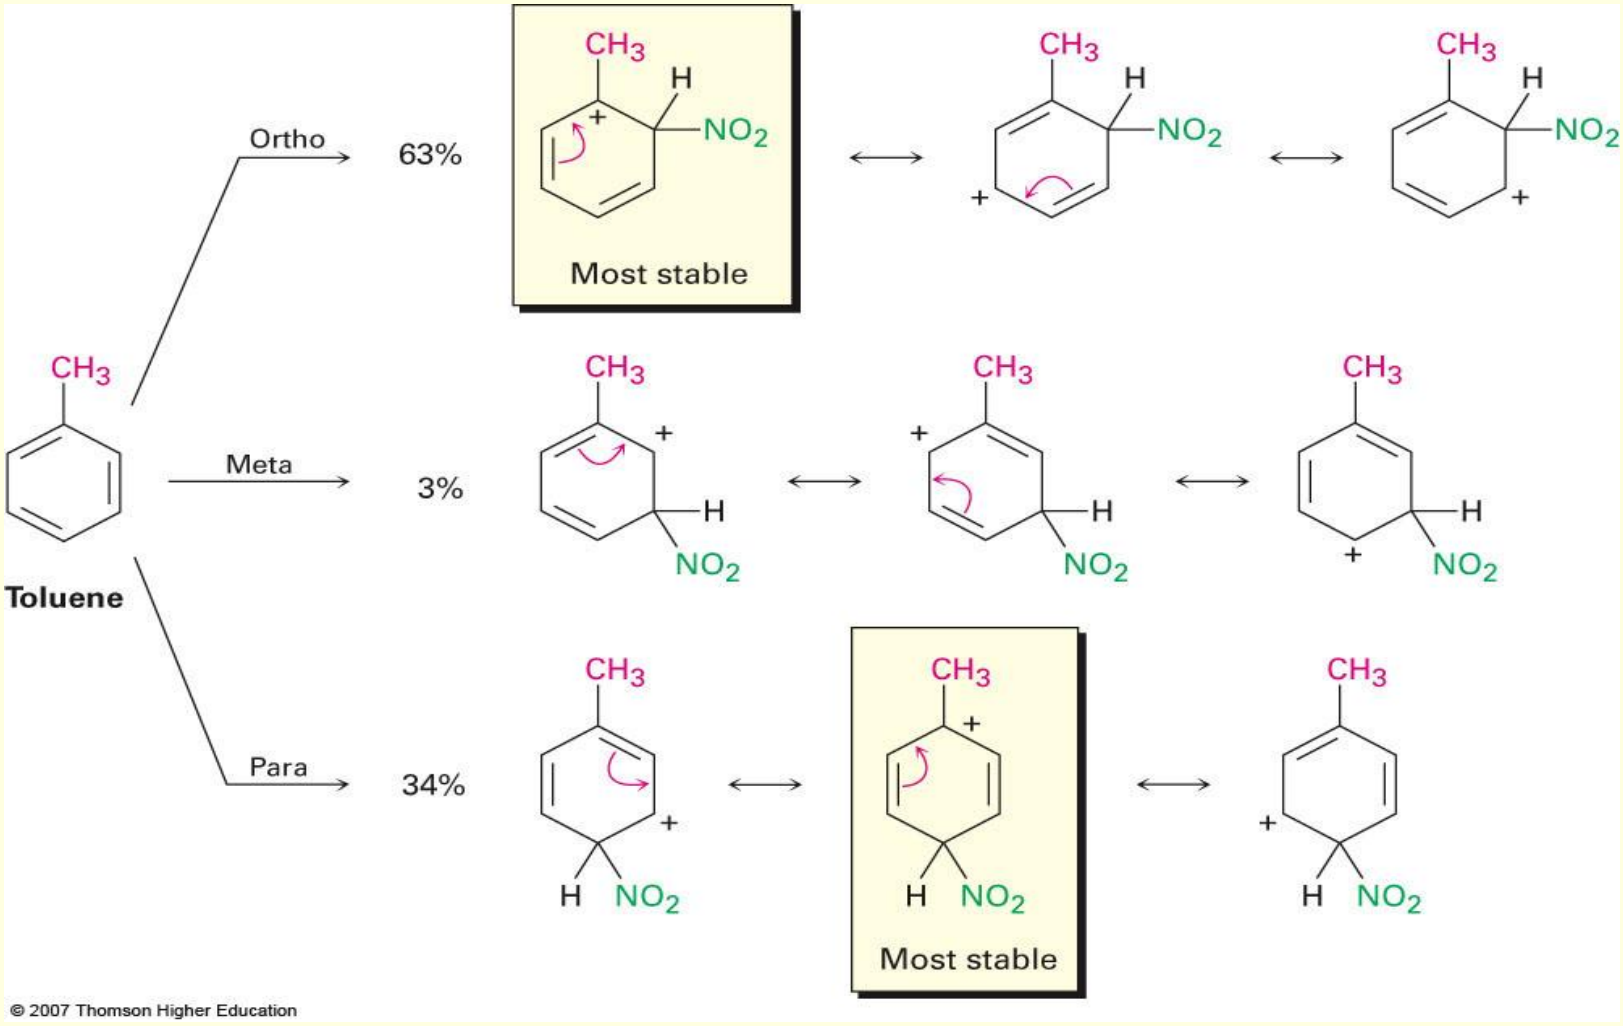
- Activating groups donate electrons to the ring, stabilizing the carbocation intermediate
- Deactivating groups withdraw electrons from the ring, destabilizing carbocation intermediate





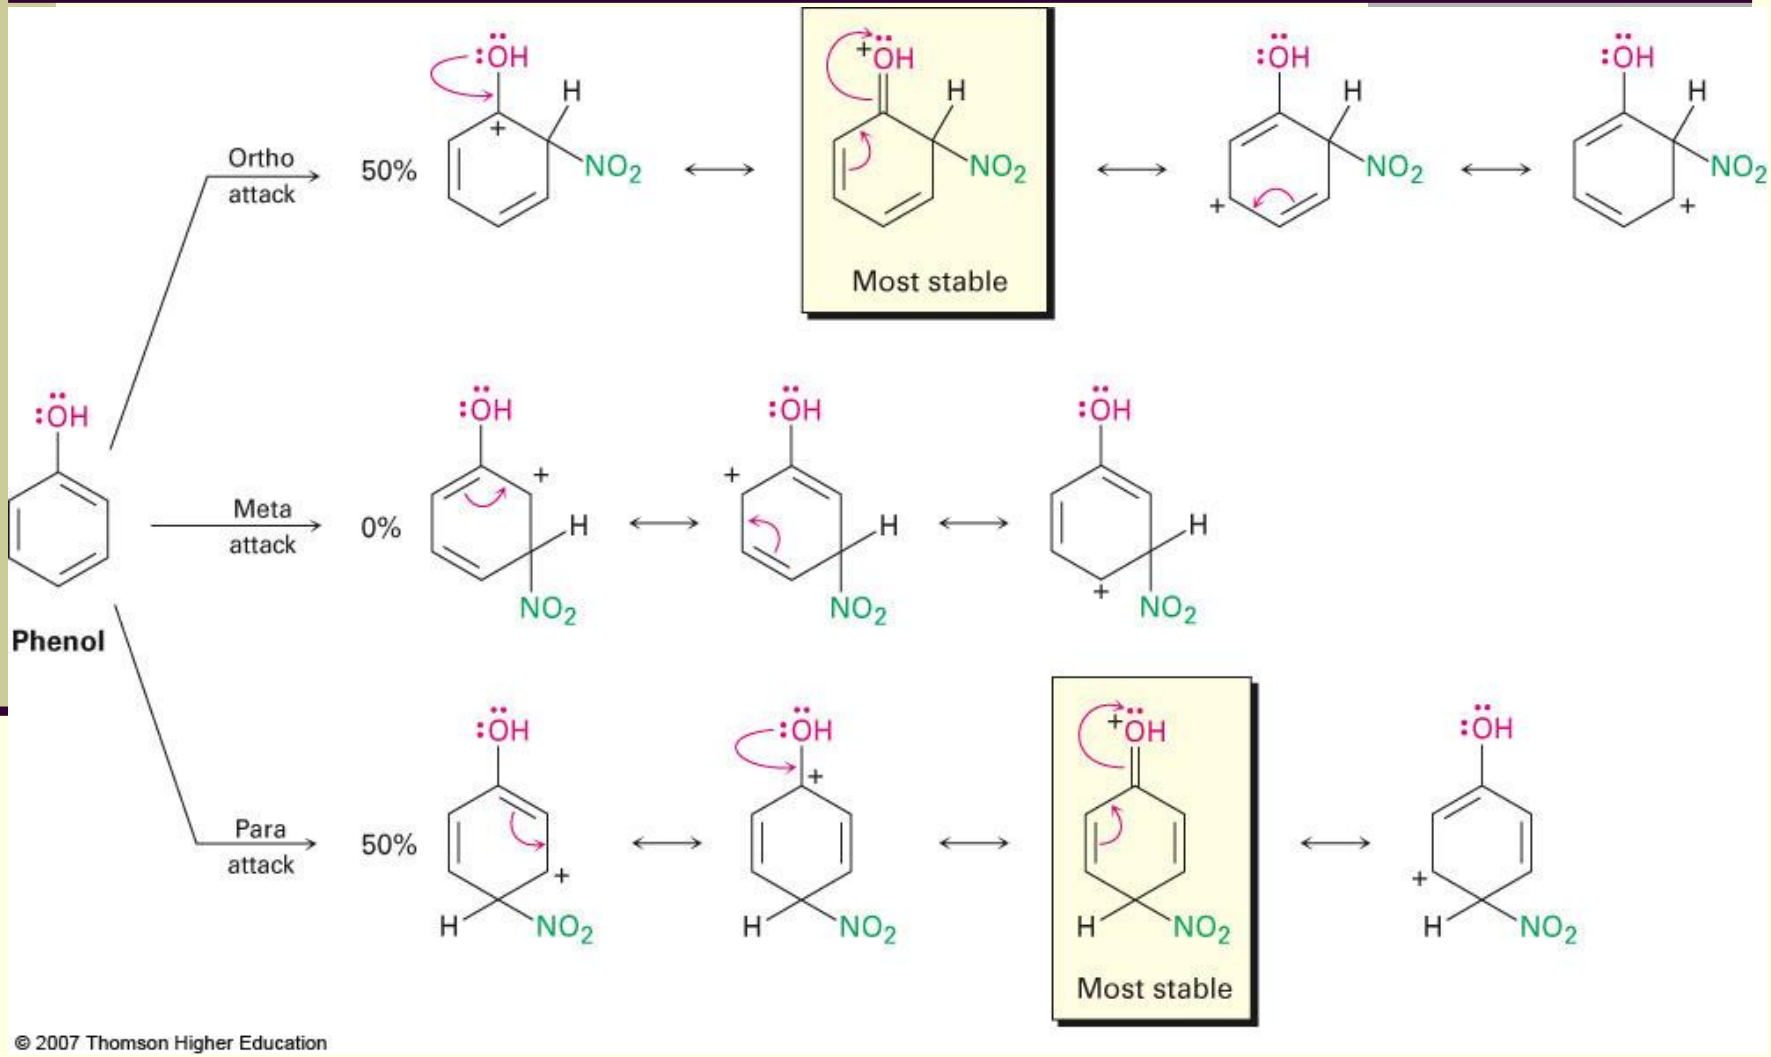
Ortho/Para-Directing Activators: Alkyl Groups

- Alkyl groups activate by induction: direct further substitution to positions ortho and para to themselves
- Alkyl group has most effect on the ortho and para positions



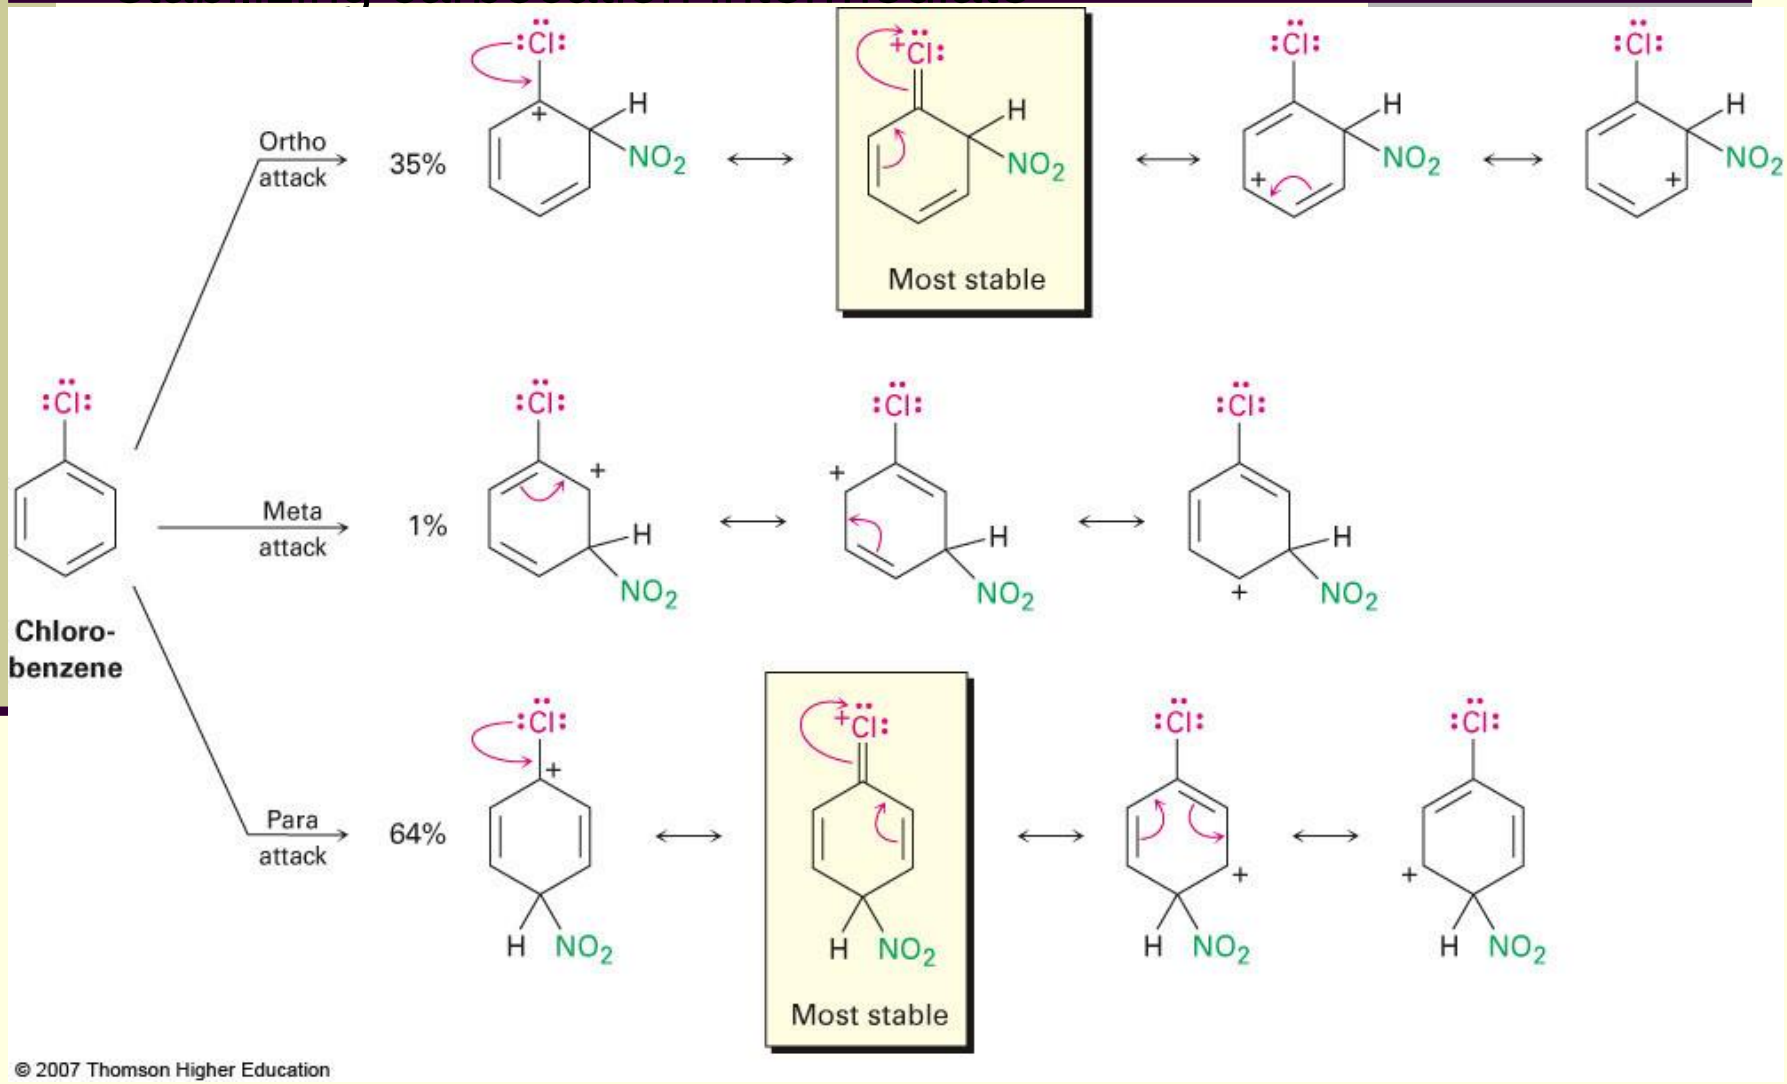
Ortho/Para-Directing Activators: OH and NH_2

- Alkoxyl, and amino groups have a strong, electron-donating resonance effect
- Most pronounced at the ortho and para positions



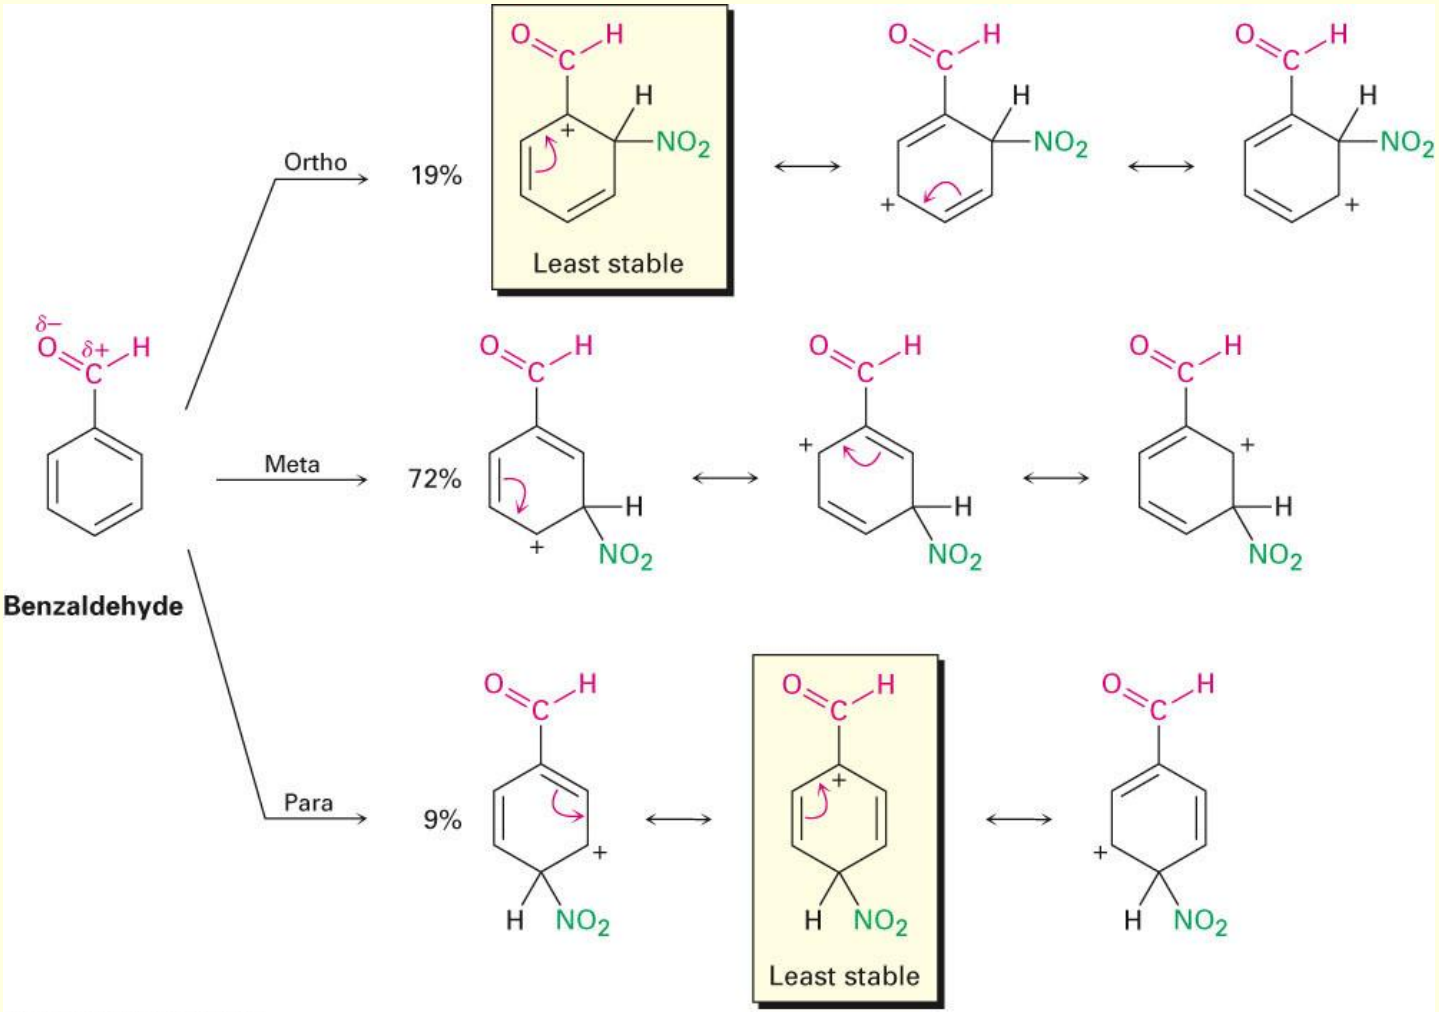
Ortho/Para-Directing Deactivators: Halogens

- Electron-withdrawing inductive effect outweighs weaker electron-donating resonance effect
- Resonance effect is only at the ortho and para positions, stabilizing carbocation intermediate



Meta-Directing Deactivators

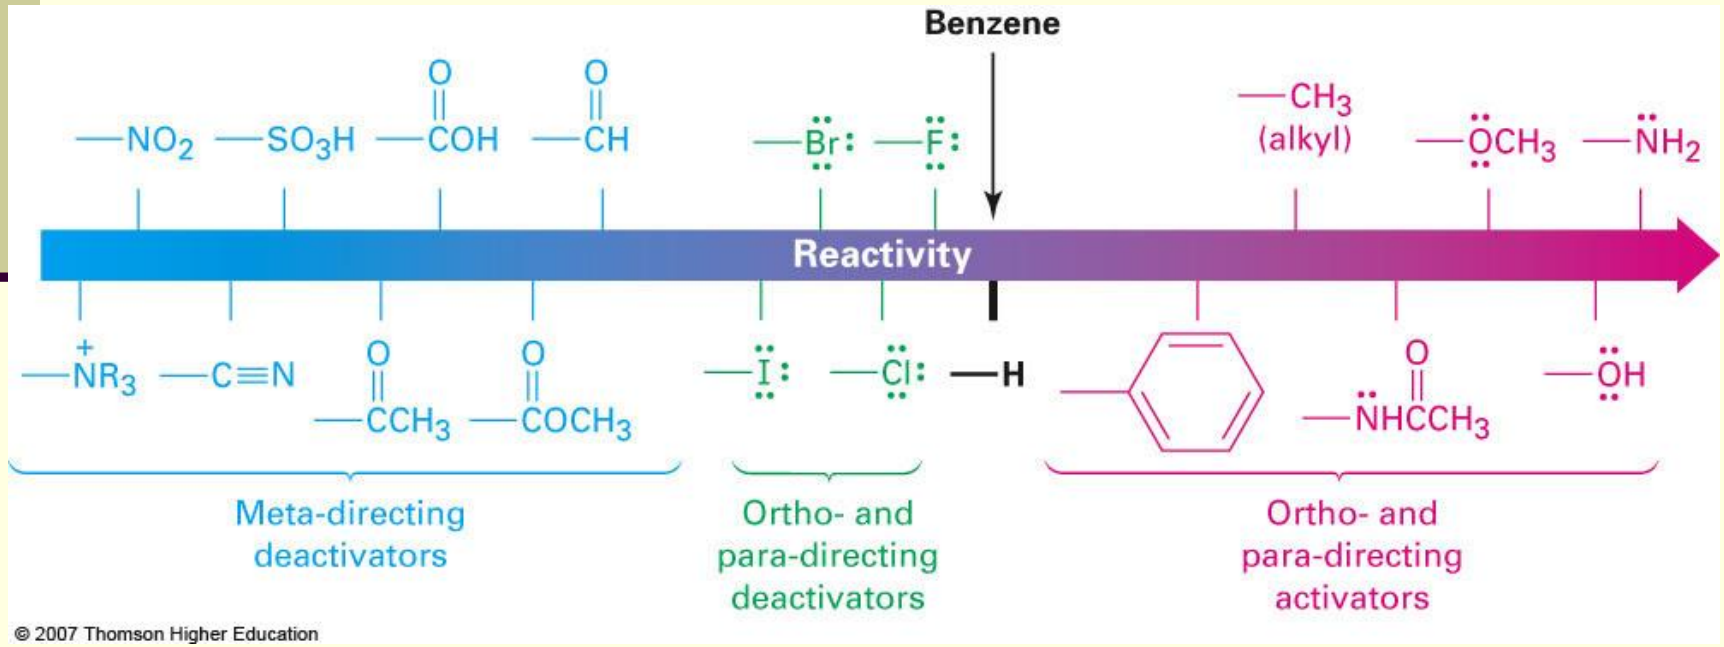
- Inductive and resonance effects reinforce each other
- Ortho and para intermediates destabilized by deactivation of carbocation intermediate
- Resonance cannot produce stabilization



Summary Table: Effect of Substituents in Aromatic Substitution

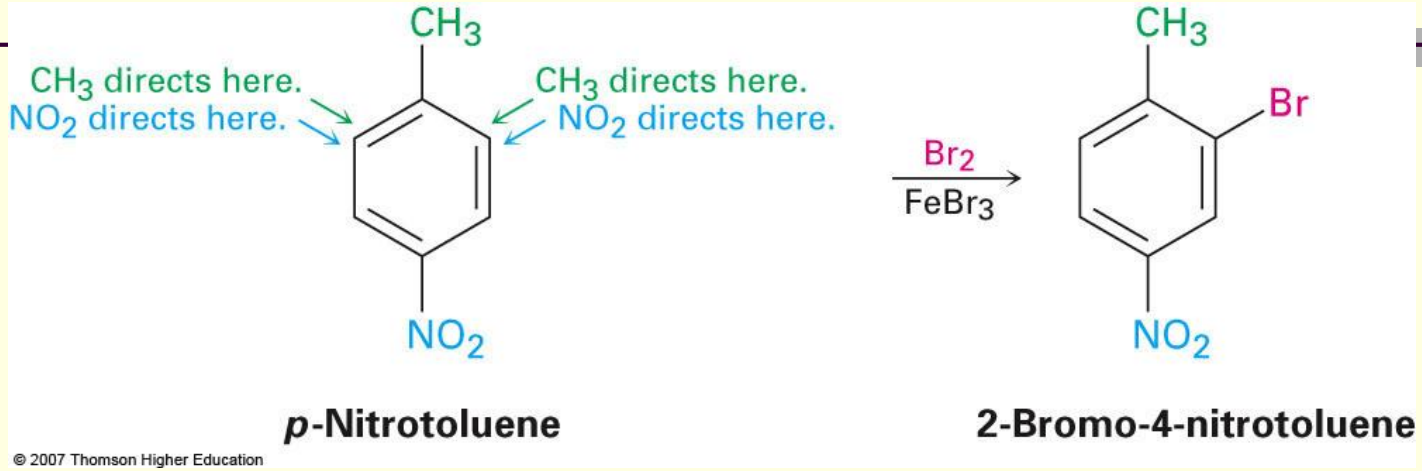
Table 16.2 Substituent Effects in Electrophilic Aromatic Substitution

Substituent	Reactivity	Orienting effect	Inductive effect	Resonance effect
$-CH_3$	Activating	Ortho, para	Weak donating	—
$-OH$, $-NH_2$	Activating	Ortho, para	Weak withdrawing	Strong donating
$-F$, $-Cl$ $-Br$, $-I$	Deactivating	Ortho, para	Strong withdrawing	Weak donating
$-NO_2$, $-CN$, $-CHO$, $-CO_2R$ $-COR$, $-CO_2H$	Deactivating	Meta	Strong withdrawing	Strong withdrawing

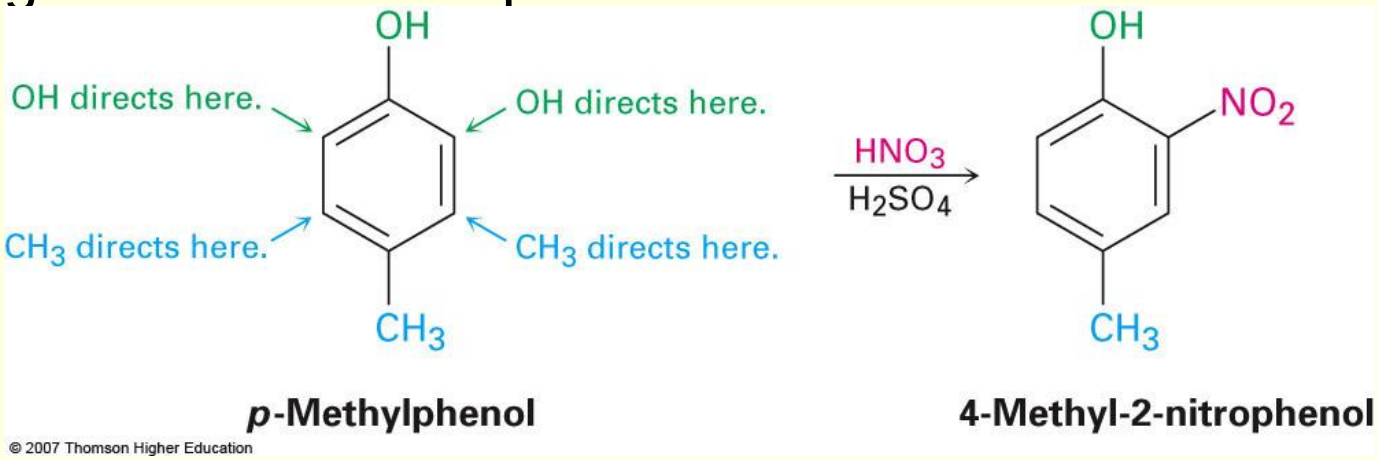


Trisubstituted Benzenes: Additivity of Effects

- If the directing effects of the two groups are the same, the result is additive

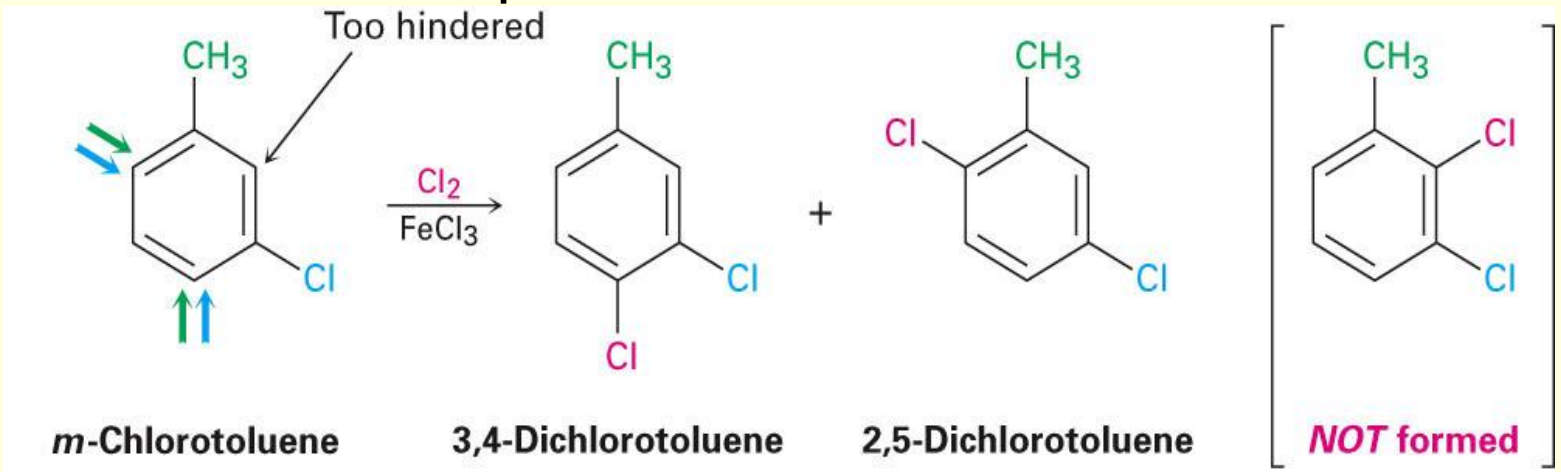


- If the directing effects of two groups oppose each other, the more powerful activating group decides the principal outcome
- Usually gives mixtures of products

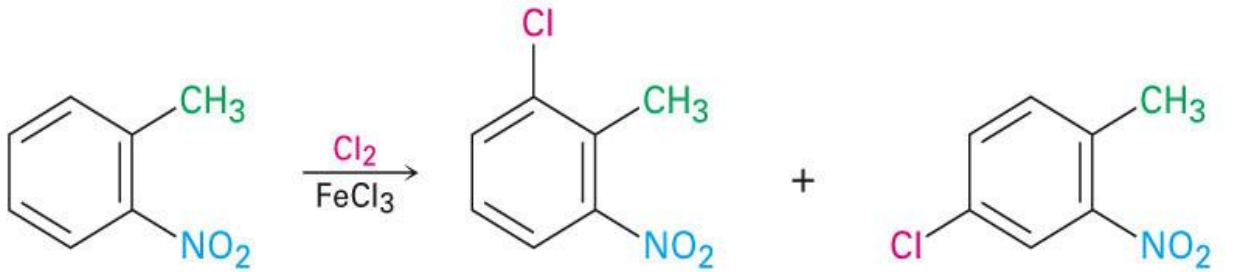


Meta-Disubstituted Compounds

- The reaction site is too hindered
- To make aromatic rings with three adjacent substituents, it is best to start with an ortho-disubstituted compound

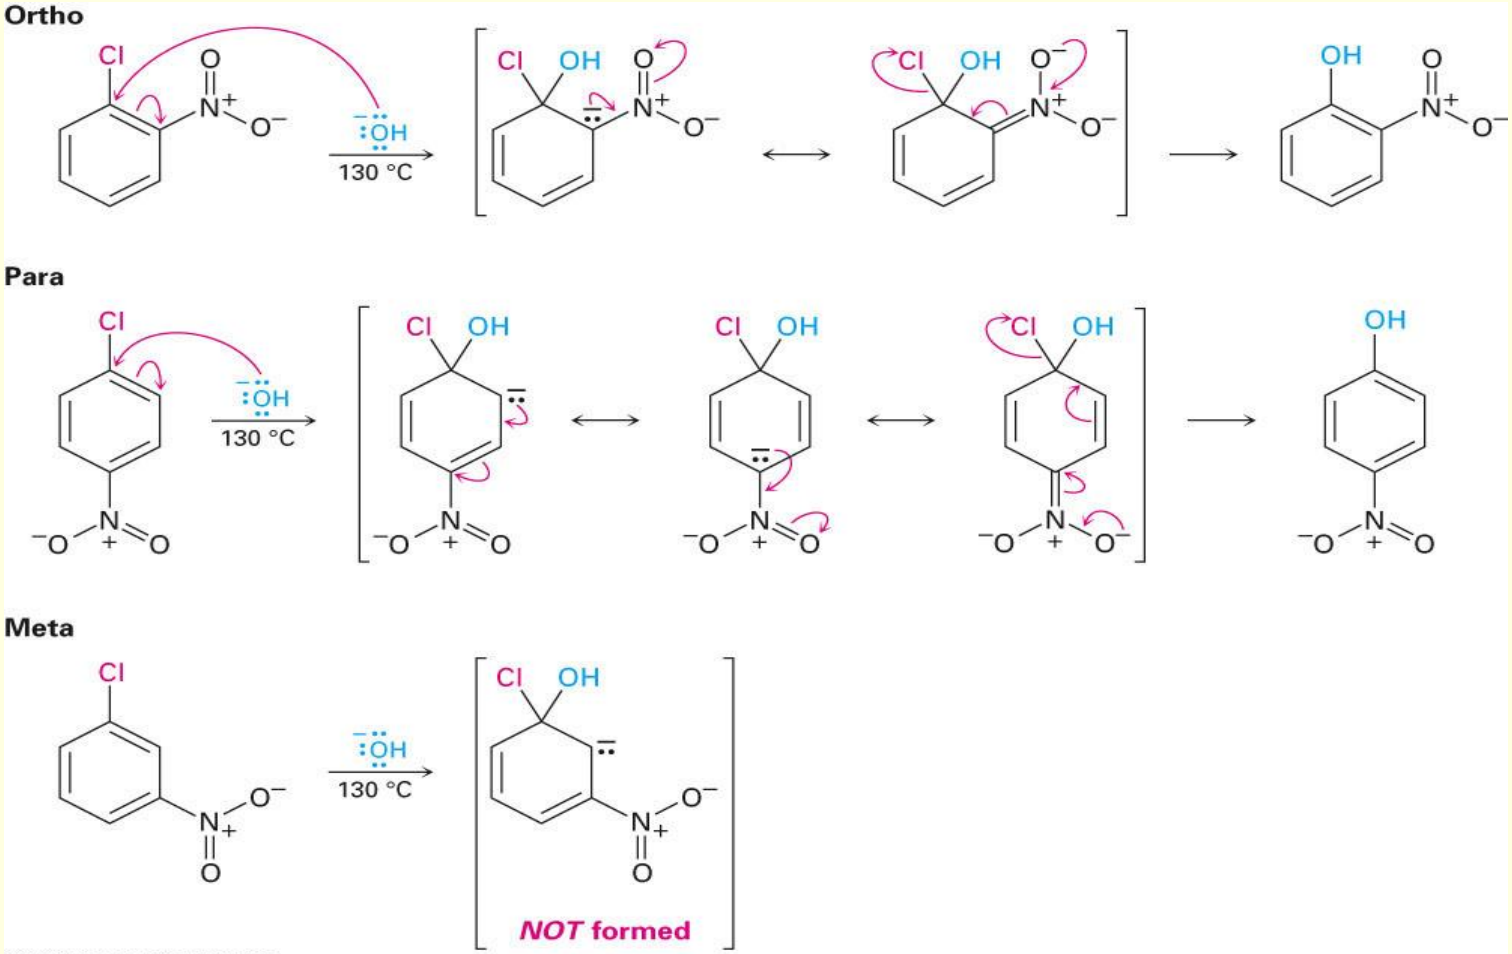


But:



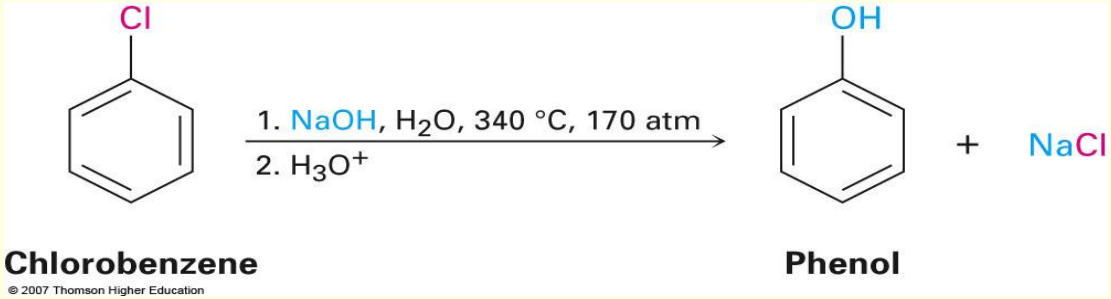
Nucleophilic Aromatic Substitution

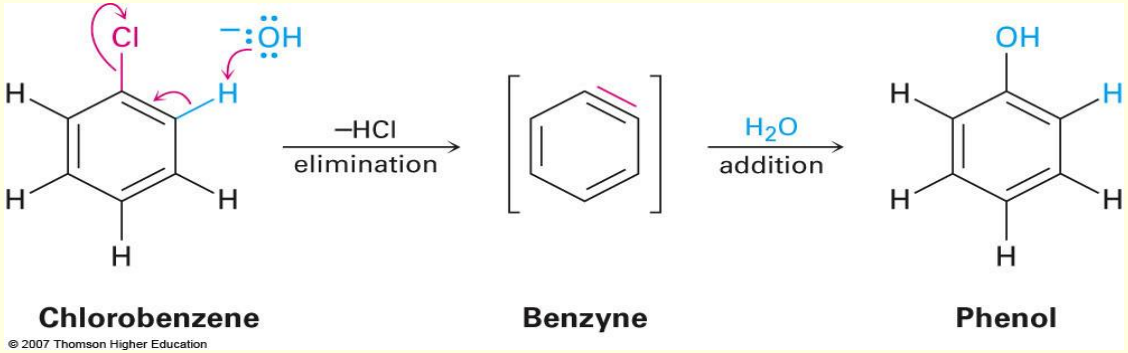
- Aryl halides with electron-withdrawing substituents ortho and para react with nucleophiles (electron withdrawing needed to accept electrons from the nucleophile)
- Form addition intermediate (Meisenheimer complex) that is stabilized by electron-withdrawal. Halide is leaving group.

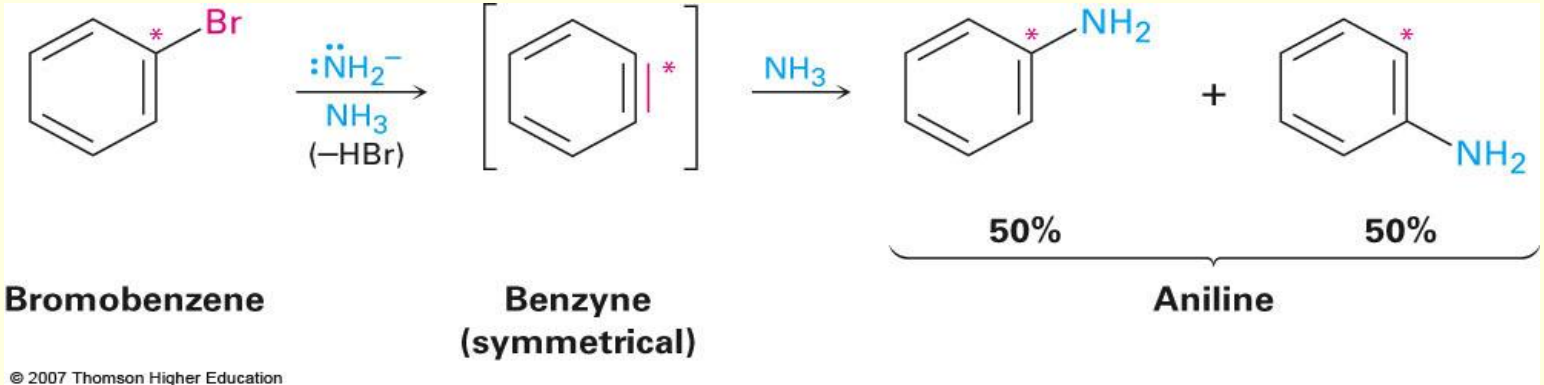


Benzyne: Substitution of Unactivated Aromatics

- Phenol is prepared industrially by treatment of chlorobenzene with dilute aqueous NaOH at 340°C under high pressure
- The reaction involves an elimination reaction that gives a triple bond in the ring: benzyne

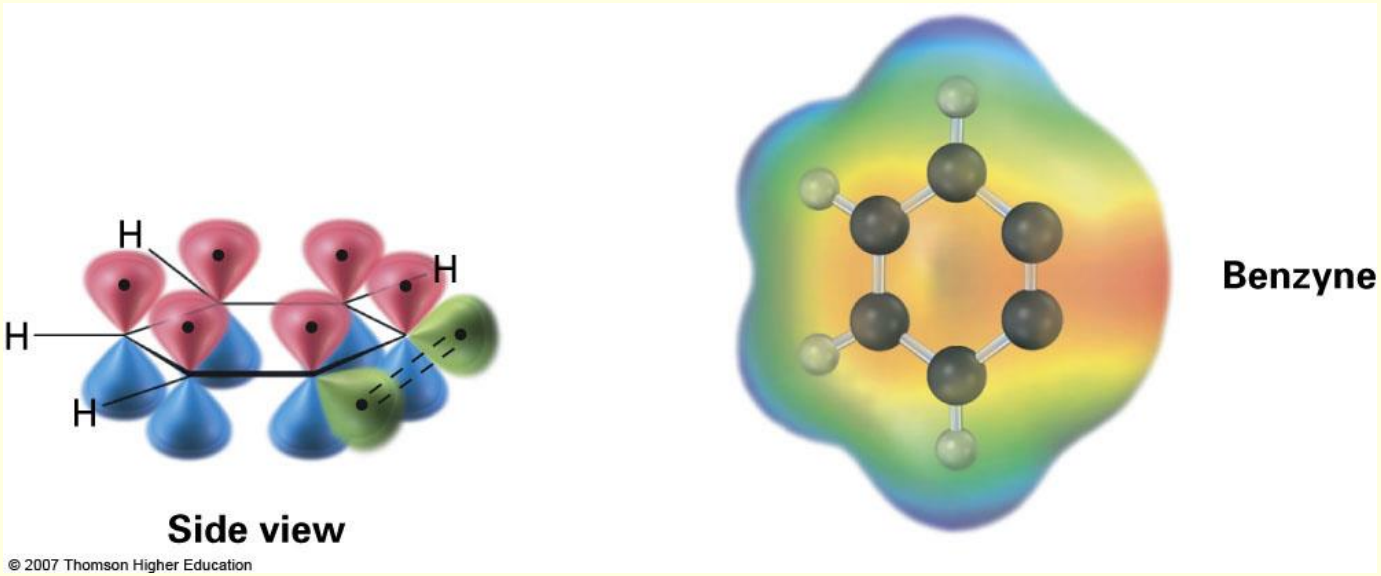






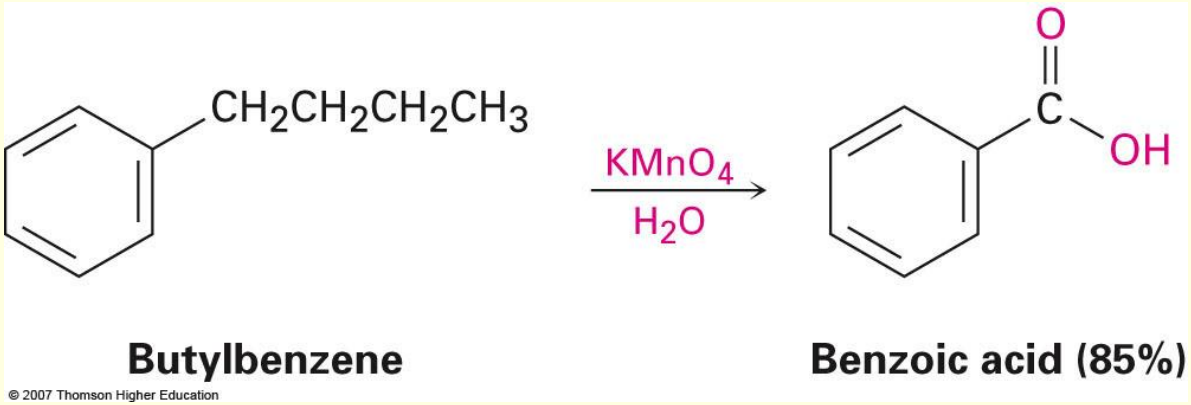
Structure of Benzyne

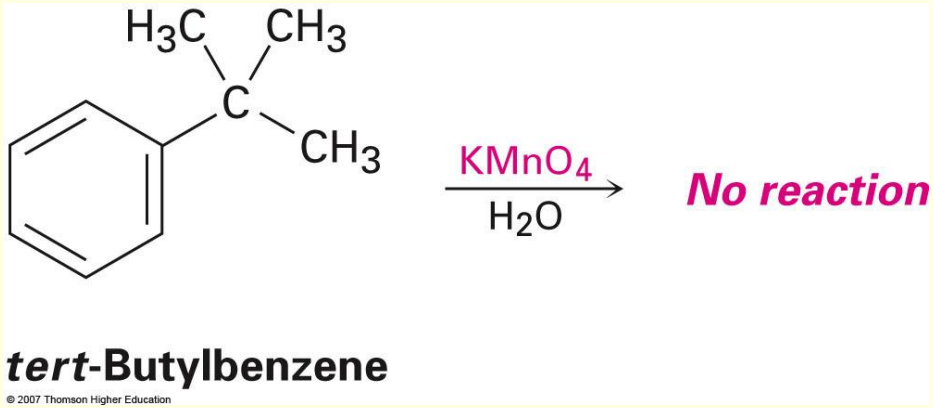
- Benzyne is a highly distorted alkyne
- The triple bond uses sp^2-hybridized carbons, not the usual sp
- The triple bond has one π bond formed by p–p overlap and another by weak sp^2–sp^2 overlap



Oxidation of Aromatic Compounds

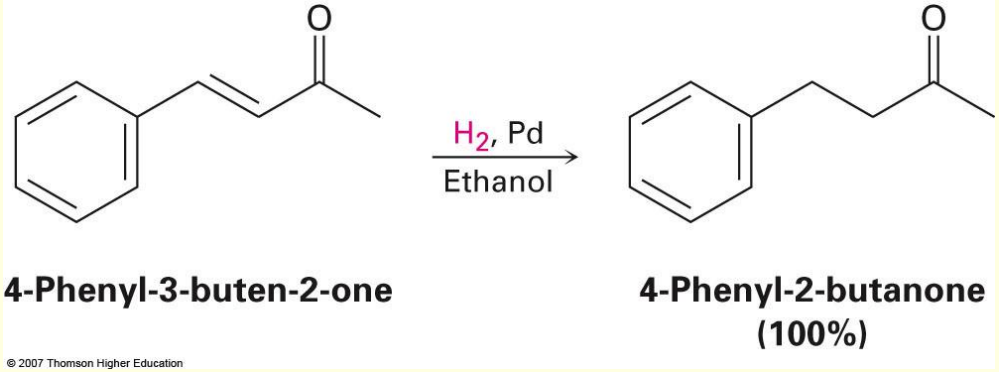
- Alkyl side chains can be oxidized to —CO_2H by strong reagents such as $KMnO_4$ if they have a C-H next to the ring
- Converts an alkylbenzene into a benzoic acid, Ar—R → Ar—CO_2H
- A benzylic C-H bond is required, or no reaction takes place



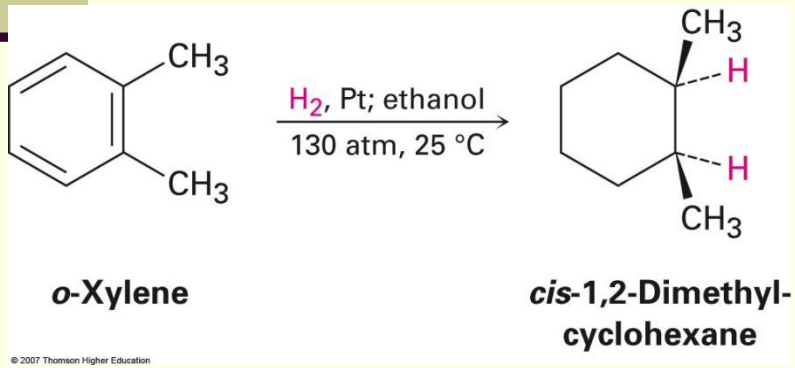


Reduction of Aromatic Compounds

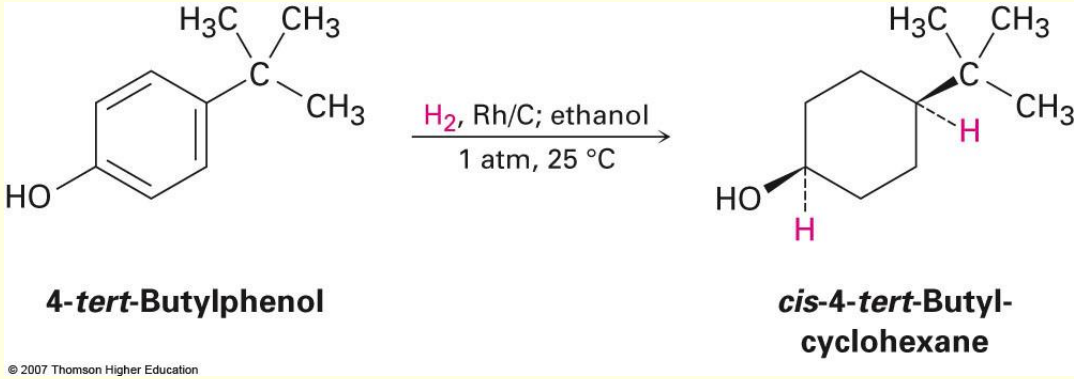
- Aromatic rings are inert to catalytic hydrogenation under conditions that reduce alkene double bonds
- Can selectively reduce an alkene double bond in the presence of an aromatic ring
- Reduction of an aromatic ring requires more powerful reducing conditions (high pressure or rhodium catalysts)



4-Phenyl-3-buten-2-one → **4-Phenyl-2-butanone (100%)**



***o*-Xylene** → ***cis*-1,2-Dimethylcyclohexane**



4-*tert*-Butylphenol → ***cis*-4-*tert*-Butylcyclohexane**

Synthesis of Trisubstituted Benzenes

- These syntheses require planning and consideration of alternative routes
- Ability to plan a sequence of reactions in right order is valuable to synthesis of substituted aromatic rings
